## List of Acronyms and Abbreviations

| AABM | Aggregate Abundance Based Management | MEF | Mid-eye to Tail Fork |
| :---: | :---: | :---: | :---: |
| ADF\&G | Alaska Department of Fish and Game | MOC | Mid-Oregon Coast |
| AI | Abundance Index | MR | Mark-Recapture |
| AUC | Area-Under-the-Curve | MRE | Mature-Run Equivalent |
| B.C. | British Columbia | MSF | Mark Selective Fishery |
| BEG | Biological Escapement Goal | MSY | Maximum Sustainable Yield |
| BY | Brood Year | NBC | Northern British Columbia |
| CBC | Central British Columbia | NEVI | North East Vancouver Island |
| CI | Confidence Interval | NMFS | National Marine Fisheries Service |
| CU | Conservation Unit | NOAA | National Oceanic and Atmospheric |
| CMRE | Cumulative Mature-Run Equivalent |  | Administration |
| CNR | Chinook Nonretention | NOC | North Oregon Coast |
| C | Committee on the Status of Endangered | NWVI | North West Vancouver Island |
| COSEWIC | Wildlife in Canada | NOR | Natural-Origin spawner |
| CPUE | Catch-per-unit-effort | NWIFC | Northwest Indian Fisheries Commission |
| CR | Chinook Retention | ODFW | Oregon Department of Fish and Wildlife |
| CRITFC | Columbia River Intertribal Fish | PFMA | Pacific Fishery Management Areas |
| CRITFC | Commission | PFMC | Pacific Fishery Management Council |
| CSAP | Canadian Centre for Science Advice Pacific | PSC | Pacific Salmon Commission |
| CTC | Chinook Technical Committee | PST | Pacific Salmon Treaty |
| CU | Canadian Conservation Units |  | Quinault Department of Natural |
| CV | Coefficient of Variation | QDNR | Resources |
| CWT | Coded-Wire Tag | rm | River Mile |
| CY | Calendar Year | SARA | Canadian Species at Risk Act |
| CYER | Calendar Year Exploitation Rate | SEAK | Southeast Alaska-Cape Suckling to Dixon |
| DFO | Fisheries and Oceans Canada |  | Entrance |
| DSL | Discounted Survey Life | SIM | Sublegal Incidental Mortality |
| DU | Canadian Designatable Units | Smsy | Escapement producing MSY |
| ELS | Electronic Tagging System | SSP | Sentinel Stocks Program |
| EO | Economic Opportunity fishery | SWVI | South West Vancouver Island |
| ER | Exploitation Rate | t. run | Terminal run |
| ESA | U.S. Endangered Species Act | TBD | To Be Determined |
| FNC | First Nations Caucus | TBR | Transboundary Rivers |
| FSC | Food, Social, and Ceremonial | tGMR | Transgenerational Genetic MarkRecapture |
| FW | Freshwater | TM | Total Mortality |
| GHL | Guideline Harvest Level | U.S. | United States |
| GMR | Genetic Mark-Recapture | UGS | Upper Strait of Georgia |
| GW | Gitwinksihlkw | UmsY | Exploitation Rate at MSY |
| IM | Incidental Mortality | UMT | Upper Management Threshold |
| iREC | Internet Recreational Effort and Catch |  | West Coast Vancouver Island excluding |
| ISBM | Individual Stock Based Management | WCVI | Area 20 |
| LAT | Low Abundance Threshold | WDFW | Washington Department of Fish and |
| LC | Landed Catch |  | Wildlife |
| LIM | Legal Incidental Mortality |  |  |

Executive Summary .....  1

1. Catch ..... 5
1.1 Review of Aggregate Abundance Based Management Fisheries ..... 6
1.1.1 Southeast Alaska Fisheries ..... 7
1.1.1.1 Troll Fisheries Catch ..... 8
1.1.1.2 Net Fisheries Catch ..... 9
1.1.1.3 Sport Fishery Catch ..... 9
1.1.1.4 Alaska Hatchery Add-on and Treaty Catch ..... 10
1.1.2 British Columbia Fisheries ..... 12
1.1.2.1 Northern British Columbia AABM ..... 12
1.1.2.1.1 Northern British Columbia Troll Fishery Catch ..... 12
1.1.2.1.2 Northern British Columbia Sport Fishery Catch. ..... 13
1.1.2.2 West Coast Vancouver Island AABM ..... 13
1.1.2.2.1 West Coast Vancouver Island Troll Fishery Catch ..... 13
1.1.2.2.2 West Coast Vancouver Island Sport Fishery Catch ..... 14
1.2 Estimates of Incidental Mortalities in AABM Fisheries ..... 14
1.2.1 Southeast Alaska Fisheries ..... 14
1.2.2 British Columbia Fisheries ..... 15
1.2.2.1 Northern British Columbia Fisheries ..... 16
1.2.2.2 West Coast Vancouver Island Fisheries ..... 16
1.3 Review of Individual Stock Based Management Fisheries ..... 16
1.3.1 Canadian Individual Stock Based Management Fisheries ..... 17
1.3.2 Southern US Individual Stock Based Management Fisheries ..... 18
1.3.2.1 Strait of Juan de Fuca and the San Juan Islands. ..... 19
1.3.2.2 Puget Sound ..... 19
1.3.2.3 Washington Coast Terminal. ..... 19
1.3.2.4 North of Cape Falcon ..... 20
1.3.2.5 Columbia River ..... 20
1.3.2.6 Oregon Coast Terminal ..... 20
1.3.3 Estimates of Incidental Mortality for Southern U.S. Fisheries ..... 21
1.4 Summary of Coastwide Landed Catch, Incidental Mortality, and Total Mortality in PSC Fisheries ..... 21
2. Chinook Salmon Escapements ..... 25
2.1 Escapement Goal Assessments ..... 25
2.2 Trends for Escapement Indicator Stocks ..... 28
2.2.1 Escapement Trends for Southeast Alaska Stocks ..... 29
2.2.2 Escapement Trends for Transboundary Stocks ..... 29
2.2.3 Escapement Trends for Canadian Stocks ..... 30
2.2.4 Escapement Trends for Washington Stocks ..... 31
2.2.5 Escapement Trends for Columbia River/Oregon Stocks ..... 32
2.3 Profiles for Escapement Indicator Stocks ..... 33
2.3.1 Southeast Alaska Stocks ..... 33
2.3.1.1 Situk River ..... 34
2.3.1.2 Chilkat River ..... 35
2.3.1.3 Unuk River ..... 36
2.3.2 Transboundary River Stocks ..... 38
2.3.2.1 Alsek River ..... 38
2.3.2.2 Taku River ..... 39
2.3.2.3 Stikine River ..... 41
2.3.3 Canadian Stocks ..... 42
2.3.3.1 Northern British Columbia ..... 42
2.3.3.1.1 Nass River ..... 42
2.3.3.1.2 Skeena River ..... 44
2.3.3.2 Central British Columbia ..... 46
2.3.3.2.1 Rivers Inlet ..... 46
2.3.3.2.2 Atnarko River ..... 48
2.3.3.3 West Coast Vancouver Island and Strait of Georgia ..... 50
2.3.3.3.1 West Coast Vancouver Island ..... 50
2.3.3.3.2 Upper Strait of Georgia ..... 54
2.3.3.3.3 Lower Strait of Georgia. ..... 55
2.3.3.4 Fraser River Stocks ..... 57
2.3.3.4.1 Fraser River Spring Run: Age 1.3 ..... 59
2.3.3.4.2 Fraser River Spring Run: Age 1.2 ..... 60
2.3.3.4.3 Fraser River Summer Run: Age 1.3 ..... 62
2.3.3.4.4 Fraser River Summer Run: Age 0.3 ..... 64
2.3.3.4.5 Fraser River Late Run (Harrison River) ..... 66
2.3.4 Puget Sound, Coastal Washington, Columbia River, and Coastal Oregon Stocks ..... 67
2.3.4.1 Puget Sound ..... 68
2.3.4.1.1 Nooksack River ..... 68
2.3.4.1.2 Skagit River Spring ..... 70
2.3.4.1.3 Skagit River Summer/Fall ..... 71
2.3.4.1.4 Stillaguamish River ..... 73
2.3.4.1.5 Snohomish River ..... 75
2.3.4.1.6 Lake Washington ..... 77
2.3.4.1.7 Green River ..... 78
2.3.4.2 Coastal Washington ..... 80
2.3.4.2.1 Hoko River ..... 80
2.3.4.2.2 Quillayute River Summer ..... 81
2.3.4.2.3 Quillayute River Fall ..... 82
2.3.4.2.4 Hoh River Spring/Summer ..... 83
2.3.4.2.5 Hoh River Fall ..... 84
2.3.4.2.6 Queets River Spring/Summer ..... 85
2.3.4.2.7 Queets River Fall ..... 87
2.3.4.2.8 Grays Harbor Spring ..... 88
2.3.4.2.9 Grays Harbor Fall ..... 89
2.3.4.3 Columbia River ..... 90
2.3.4.3.1 Mid-Columbia Summer ..... 92
2.3.4.3.2 Columbia Upriver Brights ..... 93
2.3.4.3.3 Coweeman River Tules ..... 94
2.3.4.3.4 Lewis River Fall ..... 95
2.3.4.4 Coastal Oregon ..... 96
2.3.4.4.1 North Oregon Coast ..... 96
2.3.4.4.1.1 Nehalem River ..... 97
2.3.4.4.1.2 Siletz River Fall ..... 98
2.3.4.4.1.3 Siuslaw River Fall ..... 99
2.3.4.4.2 Mid-Oregon Coast ..... 100
2.3.4.4.2.1 South Umpqua River Fall ..... 100
2.3.4.4.2.2 Coquille River Fall ..... 101
3. Stock Status ..... 104
3.1 Synoptic Evaluation of Stock Status ..... 104
3.2 Regional Trends and Profiles ..... 109
3.2.1 Southeast Alaska: Situk, Chilkat, and Unuk Rivers ..... 109
3.2.2 Transboundary Rivers: Alsek, Taku, and Stikine Rivers ..... 113
3.2.3 Canadian Stocks ..... 117
3.2.3.1 Northern British Columbia: Kitsumkalum River ..... 117
3.2.3.2 Central British Columbia: Atnarko River ..... 118
3.2.3.3 Lower Strait of Georgia: Cowichan River ..... 121
3.2.3.4 Fraser River Stocks ..... 122
3.2.3.4.1 Fraser River Spring Run Age 1.2: Nicola River ..... 123
3.2.3.4.2 Fraser River Summer Run Age 0.3: Lower Shuswap River ..... 125
3.2.3.4.3 Fraser Late Run Age 0.3: Harrison River ..... 126
3.2.4 Puget Sound, Coastal Washington, Columbia River, and Coastal Oregon Stocks ..... 128
3.2.4.1 Puget Sound ..... 128
3.2.4.2 Coastal Washington ..... 130
3.2.4.3 Columbia River ..... 136
3.2.4.3.1 Columbia River Summers ..... 136
3.2.4.3.2 Columbia River Fall ..... 137
3.2.4.4 Coastal Oregon ..... 140
3.2.4.4.1 North Oregon Coast ..... 140
3.2.4.4.2 Mid-Oregon Coast ..... 143

B. Escapements and Terminal Runs of Pacific Salmon Commission Chinook Technical Committee Chinook Salmon Escapement Indicator Stocks, 2009-2020 ..... 178Page

## ExECUTIVE Summary

The Pacific Salmon Treaty (PST) requires the Chinook Technical Committee (CTC) to provide the Pacific Salmon Commission (PSC) annual catch and escapement data for Chinook salmon stocks that are managed under the Treaty. This report contains three sections that indicate stock performance in the context of management objectives for 2020: Chinook salmon catches, escapements, and stock status.

Section 1 summarizes, for 2020, fishery catches by region and available estimates of incidental mortality (IM) by fishery, with accompanying commentary on the fisheries, management, and derivation of IM. Canada and the U.S. compile annual catch data and estimates of IM for their respective jurisdictions within the PST area according to fishery regimes, regional locations, and gear type. Landed catch (LC) is fully reported in the appendices for each geographic area covered under the PST. A summary for all PSC Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries, from 1999 to 2020, is provided in the figure below. Time series of available IM estimates are provided in Appendix A for individual fisheries. Appendix A also includes a coastwide summary of the historical time series of $L C, I M$, and their sum, total mortality (TM), across all AABM and ISBM fisheries.

Estimates of landed catch for U.S. and Canada AABM and ISBM fisheries, 1999-2020.

The preliminary estimate of Treaty LC of Chinook salmon for all PST fisheries in 2020 is 968,535 , of which 637,126 were harvested in U.S. fisheries and 331,409 were harvested in Canadian fisheries. Total estimated IM associated with this harvest is 155,007 ( $14 \%$ of the TM) in nominal fish. The TM for all PST fisheries in nominal fish was 1,123,542 Chinook salmon, which is approximately 100,655 less than recorded for 2019 (Table A25). Of the total PSC TM estimated for 2020, 722,237 occurred in U.S. fisheries and 401,305 occurred in Canadian fisheries. For U.S. fisheries, $68 \%$ of the LC and $54 \%$ of IM occurred in ISBM fisheries; in Canada, $76 \%$ of the LC and $85 \%$ of IM occurred in ISBM fisheries. For some component sport fisheries, 2020 LC and IM estimates are not yet available. Data for calculating summary information for 2020 and previous years can be found in Table A23, Table A24, and Table A25.

Section 2 includes an assessment of escapement for 52 PST escapement indicator stocks. Some of the indicator stocks are stock aggregates. There are 24 stocks that currently have PSC-agreed biologically-based goals, six of which have escapement goals defined as a range and 18 having escapement goals that are the point estimate of $\mathrm{S}_{\text {MSY }}$ (escapement producing maximum sustained yield). Annual escapements that are more than $15 \%$ below the lower end of the range or the $S_{\text {MSY point estimate are noted. The CTC will continue to review escapement goals }}$ for stocks as they are provided by respective agencies.

From 1999 to 2020, the percentage of stocks that met or exceeded escapement goals or goal ranges has varied from $41 \%$ to $96 \%$ (see figure below). In 2020, the percentage of stocks that met or exceeded goal was $79 \%$. All of the five stocks below goal were more than $15 \%$ below goal (Taku, Stikine, Unuk, Harrison, and Queets spring/summer).

Number and status of stocks with PSC-agreed escapement goals, 1999-2020.

[^0]Section 3 presents a synoptic evaluation of stock status that summarizes the performance relative to established goals over time for many of the escapement indicator stocks. This evaluation draws upon catch information (Section 1), escapement information (Section 2), and exploitation rates to evaluate the status of stocks. Synoptic plots present both the current status of stocks and the history of the stocks relative to PST management objectives; this information summarizes the performance of fisheries management relative to stocks achieving established or potential goals. The synoptic summary figure below shows that, of the 22 stocks with 2019 data and biological reference points, 16 of the stocks were in the safe zone (exploitation below $U_{\text {MSY }}$ and escapement above $S_{\text {MSY }}$ ). One stock, the Siuslaw, was in the highrisk zone. Two stocks, Atnarko and Stikine, were in the buffer zone. Three stocks were in the low escapement and low exploitation zone: Taku, Nicola, and Harrison. No stocks experienced exploitation above $U_{\text {MSY }}$ with escapements exceeding $S_{\text {MSY }}$.

Synoptic summary by region of stock status for stocks with escapement and exploitation rate data in 2019 (escapement and exploitation rate data for each stock was standardized to the stock-specific escapement goal and $U_{\text {MSY }}$ reference points).

Note: SEAK = Southeast Alaska, BC = British Columbia, TBR = Transboundary Rivers, WA/OR = Washington/Oregon, $E R=$ exploitation rate, $U_{M S Y}=$ exploitation rate at maximum sustainable yield, $S_{M S Y}$ = escapement producing maximum sustainable yield.

## 1. Саtch

The 1999 Pacific Salmon Treaty Annex and the Related Agreement (PST Agreement) substantially changed the objectives and structure of the fishery management framework by eliminating the previous ceiling and pass-through fisheries and replacing them with Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries. The 2019 PST Agreement defines catch limits based on an Abundance Index (AI) for Chinook salmon in Northern British Columbia (NBC) and West Coast Vancouver Island excluding Area 20 (WCVI) AABM fisheries. Catch limits in the Southeast Alaska-Cape Suckling to Dixon Entrance (SEAK) AABM fishery are now based on a winter troll catch-per-unit-effort (CPUE) index. The 2019 PST Agreement also requires that ISBM fisheries be managed on a national basis to meet stock-specific agreed-to maximum sustained yield (MSY) or other biologicallybased escapement objectives or to limit calendar year exploitation rates (CYER) to the levels specified in Chapter 3 Attachment I if escapement goals are not met.

In response to coastwide conservation concerns, the 2009 PST Agreement called for negotiated reductions of $15 \%$ and $30 \%$, respectively, in catches and associated harvest rates in the SEAK and WCVI AABM fisheries. The 2019 PST Agreement calls for additional sliding scale reductions in the SEAK ABBM fishery (from 7.5\% in the lowest AI tiers to $1.5 \%$ in the highest AI tier) and sliding scale reductions in the WCVI AABM fishery (from $12.5 \%$ in the lowest Al tiers to $2.5 \%$ in the highest Al tier) beyond the 2009 PST Agreement levels, as well as strengthened accountability provisions for ISBM fisheries. The revised Agreement established the CYER as a metric to evaluate performance of ISBM fisheries. If escapement goals are not being met, this metric can limit the number of fish from a particular stock that can be harvested in a given year relative to how many return to the spawning grounds in that year.

In addition, the 2019 Agreement requires an evaluation of estimates of encounters, incidental mortality (IM) and total mortality (TM) in all fisheries (Appendix A 3(a)), including:

- post-season estimates of IM that include estimates from mark selective fisheries (MSF) (paragraph 4(e)(ii)),
- TM (paragraph 4(e)(ii), Appendix A 3(b)),
- causes of significant changes in rates or patterns of IM (paragraph 4(e)(iii), Appendix A 3(c)),
- whether IM exceeds 59,400 for SEAK AABM, and 38,600 for the combined aggregate of NBC and WCVI AABM (paragraph 4(f)), and
- for ISBM fisheries, annual reporting of total adult equivalent mortality for stocks that are not meeting agreed objectives (paragraph 5(a)), or for stocks without objectives (Appendix A 11).

This section addresses these requirements. It assesses landed catch (LC), IM and TM for all PST Chinook Retention (CR) fisheries as well as those directed at other salmon species (Chinook Nonretention; CNR) in 2020. Historical LC, IM, and TM data are provided in Appendix A.

### 1.1 Review of Aggregate Abundance Based Management Fisheries

AABM fisheries for Chinook salmon are managed to a Treaty catch limit set annually preseason (2019 PST Agreement, Annex IV, Chapter 3, Tables 1 and 2). AABM fisheries are mixed stock salmon fisheries that intercept and catch migratory Chinook salmon from many stocks. There are three AABM fisheries (2019 PST Agreement, Annex IV, Chapter 3, paragraph 3 (a)):
(1) SEAK Troll, Net, and Sport,
(2) NBC Troll and Haida Gwaii Sport, and
(3) WCVI Troll and Outside Sport.

The 2009 PST Agreement specified that AABM fisheries would be managed to Treaty catch limits based on preseason Als, where a specific estimate of allowable Treaty catch corresponds to a given AI for each fishery. The 2019 PST Agreement continues the use of preseason Als for NBC and WCVI AABM fisheries and uses a CPUE-AI relationship to set preseason catch limits for the SEAK AABM fishery. Table 1.1 provides the annual preseason catch limits for all three AABM fisheries as well as an assessment of fishery performance relative to PST catch limits. Beginning in 2019, if the observed catch exceeds the preseason catch limit (overage) then the overage shall be paid back in the fishing year after the overage occurs (paragraph 6(h)(i)). In 2020, all three AABM fisheries were at or below their respective catch limits (underage).

Table 1.1-Annual catch limits, observed catches and hatchery add-ons for Aggregate Abundance Based Management (AABM) fisheries expressed in thousands of Chinook salmon. Catches exceeding preseason catch limits (overages) are shown in red; catches below preseason catch limits (underages) are in green.

| Year | Southeast Alaska (Troll, Net, Sport) |  |  | Northern British Columbia (Troll), Haida Gwaii (Sport) Treaty Catch |  | West Coast Vancouver Island (Troll, Sport) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2010 | 221.8 | 230.6 | 53.6 | 152.1 | 136.6 | 143.7 | 139.0 |
| 2011 | 294.8 | 291.2 | 65.5 | 182.4 | 122.7 | 196.8 | 204.2 |
| 2012 | 266.8 | 242.8 | 51.4 | 173.6 | 120.3 | 133.3 | 135.2 |
| 2013 | 176.0 | 191.4 | 65.6 | 143.0 | 115.9 | 115.3 | 116.9 |
| 2014 | 439.4 | 435.2 | 56.6 | 290.3 | 216.9 | 205.4 | 192.7 |
| 2015 | 237.0 | 335.0 | 68.1 | 160.4 | 158.9 | 127.3 | 119.0 |
| 2016 | 355.6 | 350.7 | 35.7 | 248.0 | 190.2 | 133.3 | 103.1 |
| 2017 | 209.7 | 175.4 | 31.6 | 149.5 | 143.3 | 115.3 | 117.4 |
| 2018 | 144.5 | 127.8 | 37.0 | 131.3 | 109.0 | 88.3 | 85.3 |
| 2019 ${ }^{3,4}$ | 140.3 | 140.3 | 34.6 | 124.8 | 88.0 | 79.9 | 73.5 |
| 2020 | 205.2 | 204.6 | 30.2 | 133.0 | 36.2 | 87.0 | 43.6 |
| 2021 | 205.2 |  |  | 133.5 |  | 88.0 |  |

${ }^{1}$ Allowable Treaty catch corresponds to the preseason abundance index.
2 Treaty catch does not include hatchery add-on or exclusions (see Table A1).
${ }^{3} 2019$ is the first year the 2019 Agreement is being implemented.
${ }^{4}$ Beginning in 2019, the SEAK preseason allowable catch is based on the CPUE method.

### 1.1.1 Southeast Alaska Fisheries

The SEAK Chinook salmon fishery is managed to stay within the annual all-gear PST total allowable catch limit determined by the SEAK early winter District 113 Troll fishery CPUE metric estimated from data collected in statistical weeks 41-48. Catch is allocated through regulations established by the Alaska Board of Fisheries among troll, net, and sport fisheries. The current allocation plan reserves 1,000 fish for set gillnet fisheries and $4.3 \%$ and $2.9 \%$ of the remaining all-gear catch is allocated to the purse seine and drift gillnet fisheries. After the net quotas are subtracted, $80 \%$ of the remainder is allocated to the commercial troll fishery and the other 20\% to sport fisheries. The commercial troll and net fisheries are managed inseason according to procedures outlined in gear-specific management plans. Sport fishery bag and possession limits as well as annual limits are established prior to the season to stay within the allowable catch, allocated as described above. Throughout the region, the commercial fishery harvest is monitored inseason using a fish ticket reporting system. Sport fishery harvests are monitored inseason using integrated data from port sampling (creel) and charter logbook reporting programs. Sampling programs are in place for all fisheries to recover coded-wire tags (CWTs) from tagged Chinook salmon and the number of Alaska hatchery fish caught is estimated, accordingly. The regulatory history and maps for each SEAK fishery are contained within annual management reports for the troll, net and sport fisheries which can be found on the Alaska Department of Fish and Game (ADF\&G) website (https://www.adfg.alaska.gov/). In addition, the SEAK AABM fishery is managed for the following:
(1) Alaska hatchery add-on (CTC 1992) and exclusion of Chinook salmon catches in selected terminal areas (CTC 2004a)
(2) compliance with provisions established by the National Marine Fisheries Service (NMFS) in accordance with the U.S. Endangered Species Act (ESA)
(3) consistency with the provisions of the PST as required by the Salmon Fishery Management Plan of the North Pacific Fishery Management Council that was established by the U.S. Magnuson-Stevens Act.

The total all-gear catch in 2020 was 234,788 , with a PST catch of 204,624 and an Alaska hatchery add-on of 30,164 (Table 1.2). The 2020 Treaty catch of 204,624 was below the 2020 CPUE-based catch limit of 205,165. SEAK Chinook salmon catch data from 1975 to 2020 are reported in Table A1.

Table 1.2-Harvest of Chinook salmon in Southeast Alaska by gear type, 2020.

| Gear | Total Catch | Alaska Hatchery Catch ${ }^{1}$ | Alaska Hatchery Add-on ${ }^{1}$ | Terminal Exclusion Catch ${ }^{2}$ | AABM Catch ${ }^{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Troll |  |  |  |  |  |
| Winter | 15,810 | 1,167 | 689 | 0 | 15,121 |
| Spring | 13,600 | 3,414 | 1,877 | 0 | 11,723 |
| Summer | 140,506 | 3,188 | 1,882 | 0 | 138,505 |
| Troll subtotal | 169,916 | 7,769 | 4,448 | 0 | 165,468 |
| Sport | 35,100 | 6,300 | 4,539 | 0 | 30,561 |
| Net |  |  |  |  |  |
| Set gillnet | 251 | 0 | 0 | 0 | 251 |
| Drift gillnet | 12,629 | 10,613 | 9,671 | 0 | 2,958 |
| Purse seine | 16,892 | 11,830 | 11,506 | 0 | 5,386 |
| Net subtotal | 29,772 | 22,443 | 21,177 | 0 | 8,595 |
| Total | 234,788 | 36,512 | 30,164 | 0 | 204,624 |
|  |  |  |  |  |  |
| CPUE-based tier catch limit = |  |  |  |  | 205,165 |
| Underage = |  |  |  |  | 541 |

Note: Annette Island Metlakatla Indian Community tribal harvest of 620 Chinook salmon are included of which 523 were Treaty fish. This includes a total tribal harvest of 91 troll, 288 drift gillnet, 241 purse seine fish, of which 91 troll, 191 drift gillnet, and 241 purse seine were Treaty fish.
${ }^{1}$ The Alaska hatchery add-on is the total estimated Alaska hatchery catch, minus 5,500 base period Alaska hatchery catch, and minus the risk adjustment (product of standard error for the total estimated Alaska hatchery catch and a risk factor of 1.282).
2 Terminal exclusion catch is a result of the harvest sharing arrangement on the Taku and Stikine rivers.
${ }^{3}$ Treaty catch is the total catch minus Alaska hatchery add-on minus terminal exclusion catch. Totals may not equal the sum of the individual values due to rounding.

### 1.1.1.1 Troll Fisheries Catch

The accounting of Treaty Chinook salmon harvested by trollers begins with the winter fishery and ends with the summer fishery. The winter troll fishery is managed for a guideline harvest level (GHL) of 45,000 non-Alaska hatchery-produced Chinook salmon, with a guideline harvest range of 43,000-47,000 non-Alaska hatchery-produced fish, plus the number of Alaska hatchery-produced Chinook salmon harvested during the winter fishery. The 2019-2020 winter troll fishery was open from October 11, 2019 through March 15, 2020. The winter troll was closed from March 16 through April 30, prior to reaching the GHL, to reduce encounters of wild SEAK and Transboundary Rivers (TBR) Chinook salmon. A total of 15,810 Chinook salmon were harvested. Of these, 1,167 (7\%) were of Alaska hatchery origin, of which 689 counted toward the Alaska hatchery add-on, resulting in a Treaty harvest of 15,121 (Table 1.2).

The spring troll fisheries target Alaska hatchery-produced Chinook salmon and are conducted along hatchery migration corridors or close to hatchery release sites. Terminal area fisheries, which begin during the spring, occur directly in front of hatcheries or at remote release sites. While there is no ceiling on the number of Chinook salmon harvested in the spring fisheries, the take of Treaty Chinook salmon is limited according to the percentage of the Alaskan hatchery fish harvested in the fishery. Non-Alaska hatchery fish are counted towards the annual Treaty catch limit of Chinook salmon, while most of the Alaska hatchery (add-on) fish are not.

The 2020 summer troll fishery included two Chinook salmon retention periods, from July 1-6 and August 15 to September 8. On August 30, prior to the completion of the second retention period target harvest, ADF\&G estimated 13,370 Chinook salmon remained on the SEAK annual all-gear Treaty catch limit. On August 31, a re-allocation of the remaining all-gear SEAK Treaty Chinook salmon to the troll fishery was authorized. The remaining Treaty allocation included unharvested fish from the commercial net fisheries and most notably the sport fishery, which was under its allocation largely due to travel restrictions associated with COVID-19. The additional fish provided another eight days of Chinook retention and contributed to a total fishery length of 25 days. A total of 140,387 Chinook salmon were harvested during summer including 91 fish harvested at Annette Island Reserve and 28 confiscated Chinook. Of this total, 3,188 (2\%) were of Alaska hatchery origin and 1,882 counted toward the Alaska hatchery addon. The resulting Treaty Chinook salmon harvest was 138,505 fish.

The total harvest for all troll fisheries in the 2020 accounting year was 169,916 Chinook salmon, of which 165,468 were Treaty Chinook salmon. This includes a total harvest of 620 in the Annette Island Metlakatla Indian Community tribal troll fishery of which 523 were Treaty Chinook salmon.

### 1.1.1.2 Net Fisheries Catch

There are three types of commercial net fisheries conducted in SEAK: purse seine, drift gillnet, and set gillnet. A total of 12,629 Chinook salmon were harvested in the drift gillnet fisheries in 2020, of which 10,613 (84\%) were of Alaska hatchery origin and 9,671 counted toward the Alaska hatchery add-on, resulting in a Treaty harvest of 2,958 fish (Table 1.2). A total of 16,892 Chinook salmon were harvested in the purse seine fisheries, of which 11,830 (70\%) were of Alaska hatchery origin and 11,506 counted toward the Alaska hatchery add-on, resulting in a Treaty harvest of 5,386 fish. A total of 251 Chinook salmon were harvested in the set gillnet fisheries, none of which were of Alaska hatchery origin, resulting in a Treaty harvest of 251 fish (Table 1.2).

With the exception of directed gillnet harvests of Chinook salmon in SEAK terminal area regulatory Districts 108 and 111 as provided for in the Transboundary Rivers chapter of the 2019 PST Agreement, harvests of Chinook salmon in net fisheries are primarily incidental to harvest of other species and only constituted a small fraction ( $<1 \%$ ) of the total net harvest of all species.

### 1.1.1.3 Sport Fishery Catch

The Southeast Alaska Chinook salmon sport fishery is managed under the directives of the Southeast Alaska King Salmon Management Plan (5 AAC 47.055). This plan prescribes management measures based upon the SEAK early winter troll CPUE metric and the harvest management plan adopted by the Alaska Board of Fisheries. In 2020, 37,900 Treaty Chinook salmon were allocated to the sport fishery. As directed by the Southeast Alaska King Salmon Management Plan, if restrictions are necessary to keep the sport fishery within its harvest allocation, nonresident anglers will be restricted first, and ADF\&G shall only restrict resident anglers if nonresident angler restrictions are insufficient to keep the sport harvest within the sport harvest allocation.

The following regulations applied during the 2020 sport fishery as dictated by the Southeast Alaska King Salmon Management Plan:

## Alaskan Resident

- The resident bag and possession limit was one Chinook salmon, 28 inches or greater in length; and
- In those inside waters where the sport fishery for Chinook salmon was closed to retention during the spring and early summer (Juneau area, Petersburg/Wrangell area, Ketchikan area), when those waters reopened the resident bag and possession limit was two Chinook salmon 28 inches or greater in length through December 31, 2020.

## Nonresident

- The nonresident bag and possession limit was one Chinook salmon, 28 inches or greater in length;
- From January 1 through June 30, a nonresident's annual catch limit was three Chinook salmon, 28 inches or greater in length;
- From July 1 through July 7, a nonresident's annual catch limit was two Chinook salmon, 28 inches or greater in length; and
- From July 1 through December 31, a nonresident's annual catch limit was one Chinook salmon, 28 inches or greater in length, and any Chinook salmon 28 inches or greater in length harvested by a nonresident from January 1 through June 30 applied toward the one fish annual catch limit.

The sport fishery was monitored closely throughout the season to ensure it stayed below the PST catch limit and the conservative harvest target. In early June, COVID-19 impacts significantly reduced Chinook salmon harvest levels, due to a reduction in nonresident angler effort. While continuing to closely monitor the sport fishery-including participation levelsthe ADF\&G initiated a series of progressively liberalized regionwide regulations beginning in mid-June of 2020 in an effort to achieve-but not exceed-the sport harvest allocation. These more liberalized regulations included increases of bag and possession limits for resident anglers as well as increases in bag, possession and annual limits for nonresident anglers. Liberalized regionwide regulations were rescinded effective September 30, 2020, at which point on October 1, 2020 the original regionwide regulations applied at the beginning of the season (noted explicitly above) per the Southeast Alaska King Salmon Management Plan took effect. The 2020 sport fishery had an estimated total harvest of 35,100 Chinook salmon, of which 30,561 counted as Treaty harvest (Table 1.2).

### 1.1.1.4 Alaska Hatchery Add-on and Treaty Catch

The yearly calculation of the Alaska hatchery add-on requires three pieces of information: the estimated total catch of Alaska hatchery-origin Chinook salmon in SEAK fisheries, a base (base level of catch) and a risk adjustment. The calculation of the add-on consists of subtracting the base and the risk adjustment from the estimated total number of Alaska hatchery Chinook salmon caught. The add-on would not be applied (assumed to be zero) if the estimated catch of Alaska hatchery produced Chinook salmon in a particular year did not exceed the sum of the risk adjustment and the base.

The total Alaska hatchery contribution estimate is the sum of multiple gear-specific contribution estimates. The non-terminal Alaska hatchery contribution estimates are estimated using expanded CWT recoveries and use "preferred" expansion strata that vary by gear and fishery using estimation procedures contained in Bernard and Clark (1996).

The risk adjustment is a penalty that is incurred due to uncertainty in the estimation of the contribution of Chinook salmon from Alaska hatcheries which results from coded-wire tagging and sampling at less than 100\%. The risk adjustment is the result of a statistical calculation (the margin of error associated with a one-sided lower confidence limit) and is inversely related to the level of coded-wire tagging of Alaska hatchery-produced Chinook salmon and to the level of CWT sampling that takes place in SEAK.

The base (or base level catch) consists of two components, a pre-Treaty base and a post-Treaty base. The original pre-Treaty base of 5,000 Chinook salmon was the estimated catch of Alaska hatchery produced Chinook salmon in SEAK fisheries in 1984 (just prior to the signing of the PST in 1985). A post-Treaty base of 500 Chinook salmon was added in 1996 to account for production of Chinook from SEAK hatcheries that began producing in the early 1990s after the signing of the Treaty. Therefore, a current base of 5,500 Chinook salmon (the sum of the preand post-Treaty base) is used in the add-on calculation each year.

The 2020 preterminal Alaska hatchery contribution to the troll fishery was 7,640 Chinook and the hatchery terminal area catch was 129 Chinook. The preterminal Alaska hatchery contribution to the net fisheries was 2,336 Chinook and the hatchery terminal area catch was 20,107. In nearly all years, the majority of the commercial hatchery terminal area Chinook catch is taken by the seine fleet and 2020 was no exception. By the time Alaska hatchery Chinook return to the hatchery terminal areas, they are no longer actively feeding and are difficult to catch using troll gear. The easiest means of harvesting the fish that have made it past the preterminal fisheries is by using seine gear. The 2020 preterminal Alaska hatchery contribution to the sport fishery was 4,300 Chinook and hatchery terminal area catch was 2,000 . Taken all together, the all-gear Alaska hatchery contribution estimate for 2020 was 36,512 Chinook and the variance of the all-gear contribution estimate was 437,892.77 (Table 1.2).

## Risk Adjustment $=$ Risk Level*Standard Error $($ AK Hatchery Contribution)

$$
=\sqrt{794,839.52} * 1.282=1,143
$$

where

Risk Level = 1.282 (a one-tail 90\% normal deviation from the mean), Therefore, the 2020 risk adjustment was: $\sqrt{437892.77} * 1.282=848$.
and

> Hatchery Add-on = AK Hatchery Contribution-Base Level Catch-Risk Adjustment $$
=41,221-5,500-1,143=34,578
$$

Therefore, the 2020 hatchery add-on was: $36,512-5,500-848=30,164$.

There were no directed terminal gillnet fisheries for Chinook near the Taku and Stikine Rivers in 2020 due to record poor returns that resulted in neither stock achieving its escapement goal. Likewise, there was no directed Chinook catch in the Situk River.

## Treaty Catch = Total Catch-Hatchery Addon-Terminal Exclusions(Situk\&TBR)

Therefore, the 2020 Treaty catch was: 234,788-30,164-0=204,624.

### 1.1.2 British Columbia Fisheries

The NBC AABM fishery includes NBC troll catch in Statistical Areas 1-5 and Haida Gwaii sport catch in Statistical Areas 1 and 2. The total NBC AABM catch in in 2020 was 36,183 (Table 1.3). The WCVI AABM fishery includes the WCVI commercial and First Nations troll and a portion of the WCVI sport fishery (defined below). The total WCVI AABM catch in 2020 was 43,581 (Table 1.4).

### 1.1.2.1 Northern British Columbia AABM

The total NBC AABM catch (troll plus sport) between October 1, 2019 and September 30, 2020 was 36,183 Chinook salmon which was below the Treaty harvest limit of 133,000 (Table 1.3).
Table 1.3-Harvest of Chinook salmon by gear for Northern British Columbia AABM fisheries, 2020.

| NBC Fishery | Landed Catch | Legal Releases | Sublegal Releases |
| :---: | ---: | ---: | ---: |
| Troll |  |  |  |
| Summer | 30,096 | 56 | 3,187 |
| CNR Troll | 0 | 5,041 | 2,123 |
| Troll subtotal | 30,096 | 5,097 | 5,310 |
| Sport | 6,087 | NA | NA |
| TOTAL | $\mathbf{3 6 , 1 8 3}$ | $\mathbf{5 , 0 9 7}$ | $\mathbf{5 , 3 1 0}$ |

### 1.1.2.1.1 Northern British Columbia Troll Fishery Catch

The NBC troll fishery landed 30,096 Chinook salmon from August 15 to September 30, 2020. The entire 2020 NBC troll fishery was conducted under a system of individual transferable quotas (ITQ). All landings of Chinook salmon caught in the NBC troll fishery were made at designated landing sites and catches were validated by an independent contractor. Validation of landings has occurred since 2005. A total of 217 licenses were issued, but the total catch was landed by 124 vessels due to quota transfers. Barbless hooks and revival boxes were mandatory in the troll fishery and the minimum size limit was 67 cm fork length ( 26.4 in ). No troll test fisheries were conducted in 2020. A ribbon boundary around Langara Island and from Shag Rock to Cape Knox on Graham Island excluded the commercial troll fishery from areas within one nautical mile of the shore from August 15 to August 31, 2020. A ribbon boundary from

Skonun Point to Shag Rock on Graham Island excluded the commercial troll fishery from areas within one nautical mile of the shore from August 15 to August 31, 2020.

### 1.1.2.1.2 Northern British Columbia Sport Fishery Catch

Sport-caught Chinook salmon from Haida Gwaii (Pacific Fishery Management Areas [PFMA] 1, 2, 101, 102 and 142) are included in the AABM totals. Catches in the Haida Gwaii sport fisheries have been estimated since 1995 through lodge logbook programs, creel surveys, and independent observations by Fisheries and Oceans Canada (DFO) staff. The 2020 Haida Gwaii sport catch was 6,087 Chinook salmon.

### 1.1.2.2 West Coast Vancouver Island AABM

Under the 2019 PST Agreement, the WCVI AABM fishery includes the WCVI troll and the outside WCVI sport fishery (defined below). The total AABM LC in the commercial troll, outside tidal sport, and First Nations troll in 2020 was 43,581 Chinook salmon (Table 1.4) which was below the Treaty harvest limit of 87,000 (Table 1.1).

Table 1.4-Harvest of Chinook salmon by gear for West Coast Vancouver Island AABM fisheries, 2020.

| WCVI Fishery | Landed Catch | Legal Releases | Sublegal Releases |
| :--- | ---: | ---: | ---: |
| Troll |  |  |  |
| Winter | 0 | 0 | 0 |
| Spring | 0 | 0 | 0 |
| Summer | 11,305 | 20 | 659 |
| Food, social, and ceremonial | 5,000 | $\mathrm{~N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ |
| Maa-nulth | 3,709 | 115 | $\mathrm{~N} / \mathrm{A}$ |
| T'aaq-wiihak | 4,170 | $\mathrm{~N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ |
| Brooks Test Fishery | 0 | 0 | 0 |
| Troll subtotal | 24,184 | 135 | 659 |
| Sport | 19,397 | 23,536 | $\mathrm{~N} / \mathrm{A}$ |
| TOTAL | $\mathbf{4 3 , 5 8 1}$ | $\mathbf{2 3 , 6 7 1}$ | $\mathbf{6 5 9}$ |

### 1.1.2.2.1 West Coast Vancouver Island Troll Fishery Catch

The West Coast of Vancouver Island (WCVI) troll fishery is conducted in Areas 23-27, and PFMAs 123-127. The PST accounting year begins October 1 and ends September 30 which covers two domestic management planning years: June 1, 2019 to May 31, 2020 and June 1, 2020 to May 31, 2021.

The Area G Troll annual management plan is designed to maintain conservative exploitation rates on stocks of concern within established limits through the use of fishing time and area closures in conjunction with fishing effort limits. Fishery openings are planned to distribute harvests proportionately over all fishery periods subject to constraints to protect stocks of concern.

Due to domestic constraints for stocks of concern, the 2020 WCVI troll fishery was constrained from August 1 to September 15. The August and September fisheries utilized plug gear only and troll fisheries were monitored to determine encounter rates of other species and estimate
numbers of released Chinook. Biological sampling was conducted for size distributions and stock compositions (CWT, DNA and otolith samples).

From May 28 to July 4, inside one nautical mile to protect Fraser stocks and July 15 to 31 with an 80 cm restriction, and again from August 1 to September 3, 2020, the Five Nations rightsbased sale fishery occurred in portions of PFMAs 24, 26, and 124-126. The catch for 2020 commercial Area G troll fisheries was 11,305 Chinook salmon (Table 1.4). The WCVI First Nations caught an estimated 5,000 Chinook salmon in food, social, and ceremonial fisheries, and 3,709 Maa-nulth and 4,170 in the Five Nations rights-based sale fisheries. The Brooks Test Fishery did not occur in 2020. The total WCVI AABM troll catch for 2020 was 24,184 with 135 legal and 659 sublegal Chinook salmon releases.

### 1.1.2.2.2 West Coast Vancouver Island Sport Fishery Catch

The AABM sport fishery includes northwest WCVI (Areas 25-27, 125-127) from October 16 to June 30, and outside of the surf line (about one nautical mile offshore) from July 1 to October 15 , plus southwest WCVI (Areas 21, 23, 24, 121, 123, and 124) from October 16 through July 31, and outside one nautical mile offshore from August 1 to October 15 . Areas inside the surf line and outside these AABM periods are included in ISBM fishery catch.

The WCVI AABM sport fishery occurs primarily in the Barkley Sound, outer Clayoquot Sound, and Nootka Sound areas. Most fishing effort occurs from mid-July through August in northwest Vancouver Island and August through mid-September in Southwest Vancouver Island. Creel surveys were conducted from early June to mid-September. The Chinook salmon daily bag limit was two fish greater than 45 cm fork length ( 17.7 in ). Barbless hooks were mandatory. The 2020 WCVI AABM sport LC estimate during the creel period was 17,934 with an additional 1,463 Chinook caught in the non-creel periods through an Internet Recreational Effort and Catch (iREC) reporting program (Table 1.4).

### 1.2 Estimates of Incidental Mortalities in AABM Fisheries

### 1.2.1 Southeast Alaska Fisheries

Estimates of encounters and IM in SEAK fisheries are presented for 2020 in Table 1.5 and in Appendix A for prior years. Estimates were converted from total IM into Treaty IM by multiplying the total encounters by the ratio of Treaty catch to LC for each respective fishery. The 2020 troll encounters were estimated from regressions of historical encounter estimates and troll effort. The regression predicts encounters from troll effort using encounter estimates obtained from direct fishery observation programs conducted during a series of years. The CR and CNR sublegal regressions use a data series from 1998 to 2006, while the CNR legal regression uses a data series from 1985 to 1988 and 1998 to 2006 (CTC 2011). Sport fishery releases were computed from the number of Chinook salmon caught and released as recorded on the annual Statewide Catch Survey (mail-in survey) forms. Legal and sublegal CNR purse seine encounters were calculated using a modified catch per landing approach that uses the relationship between the yearly catch and the magnitudes of legal and sublegal CNR encounters for years for which direct observational data are available (CTC 2011). For the gillnet fishery,
drop-off mortality was estimated as a percentage of the LC using the region-specific drop-off rate for SEAK (CTC 2004b). Encounter estimates are multiplied by the respective IM rate from CTC (1997) to obtain estimates of IM. The estimated TM in 2020 was 243,687 nominal Treaty fish, including 204,624 LC, and 39,063 IM (Table 1.5).

Chapter 3, Paragraph 4(f) of the 2019 PST Agreement establishes a limit for the level of Treaty IM in the SEAK AABM fishery of 59,400 Chinook salmon. The 2020 Treaty IM for SEAK AABM fishery is 39,063 , which is below the 59,400 limit.

Table 1.5-Estimates of Treaty and total (includes total Treaty, terminal exclusion, and hatchery add-on catch and estimates of incidental mortality) landed catch (LC), incidental mortality (IM; in nominal numbers of fish), sublegal mortality (SIM), and total mortality (TM) in SEAK AABM fishery, 2020.

| SEAK Fishery | LC | Legal Encounters | Sublegal Encounters | Total LIM ${ }^{1}$ | Total SIM ${ }^{1}$ | Total IM | Total Mortality |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Treaty |  |  |  |  |  |  |  |
| Troll CR | 165,406 | 165,406 | 42,145 | 1,323 | 11,084 | 12,407 | 177,813 |
| Troll CNR | 0 | 22,144 | 14,665 | 4,850 | 3,857 | 8,707 | 8,707 |
| Troll Total | 165,406 | 187,550 | 56,810 | 6,173 | 14,941 | 21,114 | 186,519 |
| Sport Total ${ }^{2}$ | 30,561 | 54,321 | 57,597 | 4,878 | 9,158 | 14,036 | 44,597 |
| Gillnet | 3,210 | 3,210 | 0 | 64 | 0 | 64 | 3,274 |
| Purse seine CR | 5,448 | 5,448 | 1,043 | 0 | 895 | 895 | 6,343 |
| Purse seine CNR | 0 | 1,200 | 3,186 | 612 | 2,342 | 2,954 | 2,954 |
| Net Total | 8,657 | 9,857 | 4,229 | 676 | 3,237 | 3,913 | 12,570 |
| Treaty Total | 204,624 | 251,728 | 118,637 | 11,727 | 27,336 | 39,063 | 243,687 |
| Total SEAK |  |  |  |  |  |  |  |
| Troll CR | 169,916 | 169,916 | 43,294 | 1,359 | 11,386 | 12,746 | 182,662 |
| Troll CNR | 0 | 22,445 | 14,864 | 4,915 | 3,909 | 8,825 | 8,825 |
| Troll Total | 169,916 | 192,361 | 58,159 | 6,275 | 15,296 | 21,570 | 191,486 |
| Sport Total ${ }^{2}$ | 35,100 | 62,388 | 66,151 | 5,602 | 10,518 | 16,120 | 51,220 |
| Gillnet | 12,880 | 12,880 | 0 | 258 | 0 | 258 | 13,138 |
| Purse seine CR | 16,892 | 16,892 | 3,235 | 0 | 2,776 | 2,776 | 19,668 |
| Purse seine CNR | 0 | 3,720 | 9,879 | 1,897 | 7,261 | 9,158 | 9,158 |
| Net Total | 29,772 | 33,493 | 13,114 | 2,155 | 10,037 | 12,192 | 41,964 |
| SEAK Total | 234,788 | 288,242 | 137,424 | 14,032 | 35,851 | 49,883 | 284,671 |

${ }^{1}$ Includes drop-off mortality. LIM = Legal Incidental Mortality, SIM = Sublegal Incidental Mortality.
${ }^{2}$ Catch data are preliminary estimates from creel survey expansions; IM for the SEAK sport fishery is estimated from the preliminary LC and the previous year IM to LC ratios. Final estimates are available from mail-out surveys in October one year post fishing season and will be reported in Table A2 and Table A3 of the next annual Catch and Escapement Report.

### 1.2.2 British Columbia Fisheries

Chapter 3, Paragraph 4(f) of the 2019 PST Agreement established a 38,600 limit for Treaty IM for the combined NBC and WCVI AABM fisheries. The 2020 IM for the NBC and WCVI AABM fisheries was 10,418 , which is below the limit.

### 1.2.2.1 Northern British Columbia Fisheries

Table 1.6 summarizes estimates of LC, encounters, and associated IM by size class during CR and CNR fishing periods for the 2020 NBC AABM fishery. Releases of Chinook salmon from the NBC troll fishery are based on logbook data. Encounters from the Haida Gwaii sport fishery are based on creel survey and logbook programs. IM estimates were derived using gear- and sizespecific rates from the CTC (1997). The estimated TM for 2020 was 40,045 nominal fish, which included 36,183 LC, and 3,862 IM (Table 1.6).

### 1.2.2.2 West Coast Vancouver Island Fisheries

The estimated TM of Chinook salmon for the 2020 WCVI AABM fishery was 50,137 nominal fish, which included $43,581 \mathrm{LC}$ and 6,556 IM (Table 1.6). The estimated IM included 6,295 legal and 261 sublegal nominal Chinook salmon. Table 1.6 also summarizes encounters for these fisheries by size class during CR and CNR fisheries.

Table 1.6-Estimates of total landed catch (LC), incidental mortality (IM; in nominal numbers of fish), sublegal mortality (SIM), and total mortality (TM) in NBC and WCVI AABM fisheries, 2020.

| Fishery | LC | Legal <br> Releases | Sublegal <br> Releases | Total <br> LIM $^{\mathbf{1}}$ | Total <br> SIM $^{\mathbf{1}}$ | Total <br> IM | Total <br> Mortality |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| NBC |  |  |  |  |  |  |  |
| Troll CR | 30,096 | 56 | 3,187 | 523 | 1,261 | 1,784 | 31,880 |
| Troll CNR | 0 | 5,041 | 2,123 | 1,018 | 840 | 1,858 | 1,858 |
| Troll Total | 30,096 | 5,097 | 5,310 | 1,541 | 2,102 | 3,643 | 33,739 |

| NBC Total | 36,183 | 5,097 | 5,310 | 1,760 | 2,102 | 3,862 | 40,045 |
| WCVI |  |  |  |  |  |  |  |
| Troll CR |  | 24,184 | 135 | 659 | 438 | 261 | 699 |
| Troll CNR | 0 | 0 | 0 | 0 | 0 | 0 | 24,883 |
| Troll Total | 24,184 | 135 | 659 | 438 | 261 | 699 | 24,883 |
| Sport Total | 19,397 | 23,536 | N/A | 5,857 | N/A | 5,857 | 25,254 |
| WCVI Total | 43,581 | 23,671 | 659 | 6,295 | 261 | 6,556 | 50,137 |

${ }^{1}$ LIM $=$ Legal Incidental Mortality, SIM = Sublegal Incidental Mortality.
${ }^{2}$ Includes commercial, First Nations troll food, social, and ceremonial and Maa-nulth and T'aaq-wiihak catch and Brooks test fishery.

### 1.3 Review of Individual Stock Based Management Fisheries

ISBM fisheries include all British Columbia Chinook salmon fisheries that are not included in the NBC and WCVI AABM fisheries, and all marine and freshwater Chinook salmon fisheries in Washington and Oregon. ISBM fisheries are managed with the intent of meeting management objectives for individual stocks listed in Attachment I in Chapter 3, Annex IV, of the 2019 PST Agreement.

### 1.3.1 Canadian Individual Stock Based Management Fisheries

The Canadian ISBM fisheries include all fisheries that catch or release Chinook salmon in British Columbia that are not AABM fisheries. Catches of Alsek, Taku, and Stikine River Chinook salmon occurring in Canada are also provided, although provisions for catch sharing arrangements between Canada and the U.S. for these two transboundary river stocks are described in Chapter 1 of the 2019 Agreement. ISBM obligations are not applicable to these stocks since they are not identified in Attachment I in Chapter 3. In 2020, a total of 251,645 nominal fish were caught in Canadian ISBM fisheries in British Columbia and Canadian sections of the transboundary rivers. Total estimated IM in 2020 was 59,478 Chinook salmon. The distribution of LC and estimated IM are presented in Table 1.7. Historical catches in these fisheries are provided in Appendix Table A4, Table A7, Table A8, and Table A11 through Table A15.

Table 1.7-Landed catch and incidental mortalities in Canadian ISBM fisheries, 2020.

${ }^{1}$ FSC = food, social, and ceremonial.
${ }^{2}$ Central British Columbia (CBC) troll releases are expanded (actual releases $=$
${ }^{3}$ EO = economic opportunity.

### 1.3.2 Southern US Individual Stock Based Management Fisheries

Southern U.S. fisheries in the Treaty area south of the U.S./Canada border are managed in accordance with legal obligations under the PST, several treaties between Native American tribes and the U.S., and conservation constraints of the ESA. Two court cases in the 1970s, U.S. v. Washington and U.S. v. Oregon, litigated treaty fishing rights and set forth harvest sharing obligations. Catches herein are termed treaty tribal if harvested under these Native American Treaty fishing rights cases and non-treaty otherwise. Tribal catches not harvested under these court cases are included in non-treaty catch. Currently, all southern U.S. fisheries are ISBM fisheries (Table 1.8). Historical catches in these fisheries are provided in Table A16 through Table A22.

Table 1.8-Landed catch and incidental mortality in Southern U.S. troll, net, and sport fisheries, 2018-2020.

${ }^{1}$ WDFW Catch Record Card estimates of LC were not yet available; LC for 2020 was computed using 2017-2019 mean values. Releases for 2020 were computed using the ratio of releases to landed catch from 2019.
${ }^{2}$ The value represented by Troll is the concentrated fishery off of the mouth of the Elk River which is designed to specifically exploit returning Elk River Chinook salmon.
NF = No Fishery

### 1.3.2.1 Strait of Juan de Fuca and the San Juan Islands

The preliminary estimate of the 2020 Chinook salmon catch in Strait of Juan de Fuca (Area 4B, 5,6 , and $6 C$ ) net fisheries was 72 fish. There were 40 Chinook salmon harvested in the San Juan Islands net fisheries (Area 6A, 7, and 7A). The preliminary estimate of the 2020 Strait of Juan de Fuca treaty Indian troll fishery catch (through December 2020) is 831 Chinook salmon. The catch estimate does not include catches from Area 4B during the May to September Pacific Fisheries Management Council management period; those are included in North of Cape Falcon ocean fishery catches (see section 1.3.2.4 below). Estimates for sport fisheries in 2020 are not yet available from the Washington Department of Fish and Wildlife (WDFW) Catch Record Card accounting system; thus, the preliminary estimates of sport catches and incidental mortalities in 2020 are approximated by averages of the three preceding years. Historic catch estimates are provided for the Strait of Juan de Fuca (Table A16) and San Juan areas (Table A17).

### 1.3.2.2 Puget Sound

The preliminary estimate of the net fishery harvest of Chinook salmon in Puget Sound marine and freshwater areas (excluding Strait of Juan de Fuca and the San Juan Islands) in 2020 is 40,960 (31,676 treaty Indian, 9,284 non-Indian). The harvests in treaty Indian fisheries include a preliminary estimate of 14,426 Chinook salmon in inriver fisheries. Estimates of the sport catch in 2020 are not yet available from the WDFW Catch Record Card accounting system; thus, the preliminary estimate of sport catch reported here for 2020 is an average of the previous three years $(38,331)$. Historic catch tables for Puget Sound (exclusive of the Strait of Juan de Fuca and San Juan Islands) are provided in Table A18.

### 1.3.2.3 Washington Coast Terminal

The preliminary 2020 estimate of harvest in Washington coastal net fisheries was 22,458 Chinook salmon. Harvest in treaty Indian fisheries include 18,021 harvested in north coastal rivers (Quinault, Queets, Hoh, and Quillayute rivers) and 3,687 in Grays Harbor and the Humptulips and Chehalis rivers within the basin. The 2020 non-Indian commercial net harvest was 4 Chinook salmon in Grays Harbor and 746 from Willapa Bay.
From Grays Harbor north, sport fisheries were implemented based upon preseason state-tribal agreements and were subject to in-season adjustment. Estimates of sport fishery catches for Washington coastal terminal fishing areas in 2020 are not yet available from the Catch Record Card accounting system, but are approximated here based on the average catch from the previous three years $(10,761)$. Historic catch estimates for Washington coastal inside fisheries are shown in Table A19.

### 1.3.2.4 North of Cape Falcon

Ocean fisheries off the coasts of Washington, Oregon, and California are managed under regulations recommended by the Pacific Fishery Management Council. The fisheries north of Cape Falcon also fall under the jurisdiction of the PST. For 2020, the estimated catch of Chinook salmon in commercial troll fisheries from Cape Falcon, Oregon, to the U.S.-Canada border was 14,937 for non-treaty and treaty Indian fisheries combined. Estimated catch in the ocean sport fishery north of Cape Falcon in 2020 was 7,659 Chinook salmon. Historic catch estimates for U.S. ocean fisheries north of Cape Falcon are shown in Table A20.

### 1.3.2.5 Columbia River

Chinook salmon from the Columbia River are divided into eight stock groups for management purposes. These groups are delineated by run timing and area of origin: (1) spring run originating below Bonneville Dam, (2) spring run originating above Bonneville Dam, (3) summer run originating above Bonneville Dam, (4) fall run returning to Spring Creek Hatchery, (5) fall run originating in hatchery complexes below Bonneville Dam, (6) wild fall run originating below Bonneville Dam, (7) Upriver Bright fall run, and (8) Mid-Columbia Bright fall hatchery fish.

When comparing the IM estimates in Table 1.8 and Table A21 with IM from U.S. v. Oregon Technical Advisory Committee, WDFW, Oregon Department of Fish and Wildlife (ODFW), and Columbia River Inter-Tribal Fish Commission (CRITFC) reports, readers should keep the following in mind.
(1) The Columbia River fishery management agencies include release mortality in some of their catch estimates whereas the tables in this report show LC in terms of retained fish only.
(2) Release mortality rates used by Columbia River fishery management agencies differ from those used by the CTC for this report.
(3) The tables in this report include estimates of IM from net dropout and hook and line dropoff, whereas the Columbia River fishery management agencies do not estimate this type of mortality. In 2020, the total annual harvest for all fisheries (spring, summer, and fall, both hatchery and wild) in the Columbia River basin was 253,027 Chinook salmon. The 2020 total annual Columbia River combined net and sport harvest consisted of 26,302 spring Chinook, 18,692 summer Chinook and 208,033 fall Chinook salmon (Table 1.8).

### 1.3.2.6 Oregon Coast Terminal

Most harvest in ocean fisheries off Oregon's coast is comprised of a mixture of southern Oregon and California Chinook salmon stocks not included in the PST Agreement. These stocks usually do not migrate north into the PST fisheries to any great extent. Chinook salmon originating from Oregon streams north of Cape Blanco migrate north, and most of these populations are included in the North Oregon Coast (NOC) aggregate in the PSC Chinook model. From the mid-Oregon coast to north of Cape Blanco is a smaller population group designated as the Mid-Oregon Coastal (MOC) aggregate population. Based on CWT distribution data, NOC stocks are harvested only incidentally in Oregon ocean fisheries, while the contribution of MOC stocks to Oregon and Washington ocean fisheries is greater. Commercial catch statistics for the MOC are readily available for only one terminal ocean area troll fishery on a hatchery
supplemented stock at the mouth of the Elk River. The late season (October to December) troll fishery in the Elk River terminal troll area was closed in 2020.

Sport catch of these two stock groups occurs primarily in estuary and freshwater areas as mature fish return to spawn, and catch is reported through a punch card accounting system. Historically, these estimates become available more than two years after the current season. Within the past few years, ODFW has transitioned to a mobile phone-based tagging and reporting system referred to as Electronic Tagging System (ELS) that allows for greater accuracy and shorter reporting times, and for the first time, those terminal catch estimates of Chinook from the previous catch year are available within the PSC report publication period this year. The 2019 and 2020 catch estimates are 18,484 and 23,039 respectively (Table 1.8). These estimates are the product of both NOC and MOC aggregated catch estimates, whereas previously supplied estimates of terminal catch (2018 and previous years) only consisted of the catch occurring in the NOC. This is congruent with the catch stratification accounted for between the previous Chinook model and the current phase II Chinook model's catch accounting. Historical catch estimates for the troll fishery targeting Elk River and the estuary and freshwater sport fisheries targeting on NOC stocks are shown in Table A22.

### 1.3.3 Estimates of Incidental Mortality for Southern U.S. Fisheries

Table 1.8 shows estimates of IMs for southern U.S. fisheries in marine and river fisheries in Puget Sound, on the Washington and Oregon coast north of Cape Falcon, Oregon coast terminal fisheries, and in Columbia River fisheries. IM was calculated using the release mortality, drop-out, and drop-off mortality rates assigned for areas and gears in CTC (1997). Numbers of fish released were derived from creel interviews, voluntary trip reports, fishery monitoring, or extrapolated from similarly structured fisheries with known release information.

### 1.4 Summary of Coastwide Landed Catch, Incidental Mortality, and Total Mortality in PSC Fisheries

Table 1.9 provides a coastwide summary of Chinook salmon catches and estimates of IM and TM in PST fisheries for 2020. It should be noted, for some component fisheries, that current 2020 LC and IM are not yet available; the preliminary estimates of LC and IM will be updated in future reports as observed data become available.

The preliminary estimate of Treaty LC of Chinook salmon for all PST fisheries in 2020 is 968,535, of which 637,126 were taken in U.S. fisheries and 331,409 were taken in Canadian fisheries (Table 1.9). Total estimated IM associated with this harvest is 155,007 ( $14 \%$ of the TM) in nominal fish. The TM for all PST fisheries in nominal fish was 1,123,542 Chinook salmon, which is approximately 100,655 less than recorded for 2019 (Table A25). Of the total PSC TM estimated for 2020, 722,237 occurred in U.S. fisheries and 401,305 occurred in Canadian fisheries. For U.S. fisheries, $68 \%$ of the LC and $54 \%$ of IM occurred in ISBM fisheries; in Canada, $76 \%$ of the LC and $85 \%$ of IM occurred in ISBM fisheries. For some component sport fisheries, 2020 LC and IM estimates are not yet available. Data for calculating summary information
contained in Table 1.9 for 2020 and previous years can be found in Table A23, Table A24, and Table A25.

Table 1.9-Summary in nominal fish of preliminary estimates for landed catch (LC), incidental mortality (IM), and total mortality (TM) for U.S. and Canada Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries, 2020.

| Fishery | $\mathbf{2 0 2 0}$ |  |  |
| :--- | ---: | ---: | ---: |
|  | Landed <br> Catch | Incidental <br> Mortality | Total <br> Mortality |
| SEAK AABM | 204,624 | 39,063 | 243,687 |
| SEAK hatchery add-on and terminal exclusion | 30,164 | 10,820 | 40,984 |
| U.S. ISBM | 432,502 | 46,048 | 478,550 |
| U.S. Total $^{1}$ | 637,126 | 85,111 | 722,237 |
| NBC AABM | 36,183 | 3,862 | 40,045 |
| WCVI AABM | 43,581 | 6,556 | 50,137 |
| Canada ISBM $^{\text {Canada Total }} 1251,645$ | 59,478 | 311,123 |  |
| PST Fisheries Total $^{1}$ | 331,409 | 69,896 | 401,305 |

${ }^{1}$ Does not include SEAK AABM fishery non-Treaty catch from hatchery add-on and terminal exclusion.
Total mortality in PST fisheries since 1999 is summarized over the four broad categories of AABM and ISBM fisheries for both parties in Figure 1.1. The total mortality across all four fishery groups averaged 1,572,900 Chinook during the 1999 PST Agreement (1999-2008) and averaged 1,743,400 during the 2009 PST Agreement (2009-2018). The ISBM total mortality averages increased for both U.S. and Canadian fisheries between the two PST Agreements by approximately 205,100 fish and 12,500 fish respectively; the averages for the U.S. and Canadian AABM fishery groups decreased by approximately 41,200 in the U.S. and 5,500 in Canada. During the 1999 PST Agreement, 22\% of the average total PST-related fishery mortality occurred in U.S. AABM fisheries, $20 \%$ in Canadian AABM fisheries, $17 \%$ in Canadian ISBM fisheries, and $41 \%$ in U.S. ISBM fisheries. During the 2009 PST Agreement the distribution shifted slightly such that $18 \%$ of total mortality occurred in U.S. AABM fisheries, $18 \%$ in Canadian AABM fisheries, $16 \%$ in Canadian ISBM fisheries, and $49 \%$ in U.S. ISBM fisheries. In 2020, $22 \%$ of the average total PST-related fishery mortality occurred in U.S. AABM fisheries, $8 \%$ in Canadian AABM fisheries, $28 \%$ in Canadian ISBM fisheries, and 43\% in U.S. ISBM fisheries.

Figure 1.1-Estimates of landed catch, incidental mortality and total mortality for U.S. and Canada Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries, 1999-2020.

## 2. Chinook Salmon Escapements

The 2019 PST Agreement (Annex IV, Chapter 3, Paragraph 2(a)) establishes a comprehensive and coordinated Chinook salmon fishery management program that:
"(iii) uses harvest regimes based on annual indices of abundance that are responsive to changes in production, that take into account all fishery induced mortalities, and that are designed to meet maximum sustainable yield (MSY) or other agreed biologicallybased numeric escapement or exploitation rate objectives, including those set out in Attachment I,
(iv) contributes to the improvement in trends in spawning escapements of depressed Chinook salmon stocks and is consistent with improved Chinook salmon production",

Paragraph 2(b)(iii) and Appendix A (1)(c) direct the CTC to report annually on (1) naturally spawning Chinook stocks in relation to the agreed MSY or other agreed biologically-based escapement objectives, (2) rebuilding exploitation rate objectives, or other metrics, and (3) trends in the status of stocks and progress in rebuilding naturally spawning Chinook stocks. In addition, paragraph 7(a)(iv) directs the CTC to annually provide the Commission with:
the status concerning the achievement of stock-specific management objectives; specifically, a table of agreed-to management objectives for each stock included in Attachment I and the annual stock-specific metrics, if available, with the identification of stocks that achieved less than $85 \%$ of the point estimate (or lower end range) of the management objective for three consecutive years beginning in 2019;

Attachment I of Chapter 3 of the 2019 PST Agreement lists 37 escapement indicator stocks, including 22 stocks with escapement goals and 15 stocks with escapement goals to be determined. In addition, the Canadian Okanagan stock is being evaluated, per paragraph 5(b), for future inclusion as an indicator stock. The CTC reports on 52 indicator stocks, which are included in this chapter.

In this section of the report, the CTC provides information on escapement, escapement performance relative to PSC-agreed management objectives, and escapement trends consistent with tasks described in Chapter 3, Appendix A.

### 2.1 Escapement Goal Assessments

This section includes an assessment of escapement for 52 PST escapement indicator stocks, some of which are stock aggregates. There are currently 22 stocks in Attachment I that have management objectives; 18 of these have CTC-accepted escapement goals or escapement goal ranges ${ }^{1}$ and four have agency escapement goals that have been agreed to by the PSC but have not undergone CTC review (Atnarko, Lower Shuswap, Skagit Spring, Skagit Summer/Fall). The status and number of stocks in Attachment I with agreed management objectives for return

[^1]years 2018 through 2020 are shown in (Table 2.1). In 2020, 4 of the 22 stocks were more than 85\% below their escapement goals (i.e., Unuk, Taku, Stikine, Harrison).

Paragraph 7(a)(iv) directs the CTC to identify stocks that achieved less than $85 \%$ of the point estimate (or lower end range) of the management objective for three consecutive years. For the 2018 to 2020, the Harrison and Taku escapement indicators failed to achieve $85 \%$ of their respective escapement goals in all three consecutive years.

Table 2.1-Attachment I escapement indicator stocks, management objectives, and escapement performance, 2018-2020.

For stocks with PSC-agreed management objectives, escapements above the goal or lower bound escapement range are in green, escapements within $85 \%$ of the goal or lower bound of the escapement range are in yellow, and escapements below the $85 \%$ threshold are in red.

| Stock group | Run | Escapement Indicator | Management Objective ${ }^{1}$ | 2018 | 2019 | 2020 | $\begin{gathered} 3 \text { Yrs < } \\ 85 \% ? \end{gathered}$ |

${ }^{1}$ Management objective of "TBD" is "to be determined" after CTC review (Paragraph 2(b)(iv)).
${ }^{2}$ Identified for management of SEAK fisheries in paragraph 6(b)(iv).
${ }^{3}$ Stock specific harvest limits identified in Chapter 1 of the PST.
${ }^{4}$ Agency escapement goal has the same status as CTC-agreed escapement goal.
${ }^{5}$ NWVI Natural Aggregate consists of Colonial-Cayeagle, Tashish, Artlish, and Kaouk.
${ }^{6}$ SWVI Natural Aggregate consists of Bedwell-Ursus, Megin, and Moyeha.
${ }^{7}$ Pending the review specified in paragraph 5(b) of Chapter 3 and a subsequent Commission decision.

The status and number of stocks with agreed goals for return years 1999 through 2020 is shown in Figure 2.1. The percentage of stocks that met or exceeded escapement objectives (at or above point estimate or lower end of range) has varied between $41 \%$ and $96 \%$. In 2020, the percentage of stocks that met or exceeded goal was $79 \%$. All of the 5 stocks below goal were more than $15 \%$ below goal (Taku, Stikine, Unuk, Harrison, and Queets spring/summer).

Figure 2.1-Number and status of stocks with PSC-agreed escapement goals, 1999-2020.
Note: The Keta, Blossom, and King Salmon rivers and Andrews Creek stocks were dropped as escapement indicator stocks in 2013 and Grays Harbor fall was added in 2014. In 2019, the Deschutes and Chickamin rivers stocks were dropped and the Atnarko, Lower Shuswap. Skagit spring, and Skagit summer/fall stocks were added bringing the total number of current indicator stocks with PSC-agreed escapement goals to 24.

### 2.2 Trends for Escapement Indicator Stocks

The evaluation of escapement trends is based on the 1999 to 2020 time series of escapement using a state-space exponential growth model (Dennis et al. 2006) parameterized through restricted maximum likelihood (Humbert et al. 2009). Estimates of rates of change produced by this model are generally superior to those produced through maximum likelihood analysis alone (Staples et al. 2004). Assuming the true population size is generated by stochastic exponential growth, this method separates observation error and process noise and produces variances and confidence intervals (CIs) that fully represent the annual variability associated with environmental stochasticity, along with sampling error (Humbert et al. 2009). The first year in the time series corresponds with the start of the 1999 Agreement; however, the time series of escapement starts in 2000 for Lower Shuswap due to changes in escapement estimation methodology. The last year in the escapement time series was 2018 for Nooksack Spring (2019 and 2020 data were not available at the time of writing this report); hence the trend analysis for Nooksack was based on years 1999-2018. Stock-specific escapement trends are characterized by the long-term mean rate of change ( $\mu$ ) and corresponding $80 \%$ CIs, where $\mu=$ 0.00 represents equilibrium, indicating that escapement has been stable on average for the selected time period. Hence the mean rate of change $\mu$ quantifies the mean tendency of escapement over the selected time period. If the ratio of process noise and observation error is constant, the Cls represent the inter-annual variability in escapement rates of change (Humbert et al. 2009). Stocks are grouped into five regions: Southeast Alaska, Transboundary, British Columbia, Washington, and Columbia River/Oregon.

### 2.2.1 Escapement Trends for Southeast Alaska Stocks

Escapement trends for the Situk and Chilkat stocks within the SEAK stock group were highly variable, however not significantly different than zero (Figure 2.2). Escapement for the Unuk River stock has decreased significantly over the same time period (-6.2\%, Figure 2.2). This decline can be attributed to reduced marine survival of emigrating yearling smolt, which began with the 2006 brood year and has continued through the most recent brood years. This has resulted in below-goal escapements for the Unuk stock in 3 of the last 5 calendar years (20162020).

Figure 2.2-Long-term annual rates of change in escapements for SEAK Chinook salmon stocks. Note: Circles represent mean rate of change and bars represent $80 \%$ Cls.

### 2.2.2 Escapement Trends for Transboundary Stocks

For transboundary river stocks (Alsek, Taku, Stikine), the wide confidence intervals indicate escapement has been highly variable during the 1999-2020 period and characterized by annual rates of change fluctuating between positive and negative. Yet, mean rates of change for these stocks are slightly negative for Taku (-1.4\%), Stikine (-3.4\%), and Alsek (-4.3\%; Figure 2.3).

Figure 2.3-Long-term annual rates of change in escapements for Transboundary River Chinook salmon stocks.

Note: Circles represent mean rate of change and bars represent $80 \%$ Cls.

### 2.2.3 Escapement Trends for Canadian Stocks

Long-term rates of change in escapement for Canadian stocks were based on 1999-2020 time series of escapement for 18 of the 19 stocks evaluated. Escapement time series started in 2000 for Lower Shuswap due to changes in escapement estimation methodologies. Few Canadian stocks exhibited clearly positive or negative tendencies in long-term rates of change in escapement generally due to large variability in annual rates of change (as indicated by the $80 \%$ CIs; Figure 2.4). Twelve stocks exhibited negative mean rates of change in escapement, but these were clearly negative only for Nass (-3.6\%), Skeena (-4.0\%), and Harrison (-5.1\%). Seven stocks had positive mean rates of change, but only WCVI-14 (3.3\%) and Fraser Summer 0.3 (2.1\%) showed a clearly positive trend. Chinook salmon from Nass, Skeena, Kitsumkalum, WCVI14, Nanaimo, Fraser Summer 0.3, Harrison, and Lower Shuswap exhibited the lowest variability in annual rates of change in escapement whereas Chinook salmon from Phillips, Cowichan, and Fraser Summer 1.3 exhibited the largest variability amongst all Canadian stocks. Regional patterns in rates of change are noticeable with clear declining tendencies in escapement for Northern BC and a subset of Fraser stocks. Similarly, positive tendencies in escapement can be appreciated for Strait of Georgia stocks.

Figure 2.4-Long-term annual rates of change in escapements for Canadian Chinook salmon stocks.

Note: Circles represent mean rate of change and bars represent $80 \%$ Cls. Escapement time series for Lower Shuswap started in 2000.

### 2.2.4 Escapement Trends for Washington Stocks

Escapement trends between 1999 and 2020 revealed several noteworthy patterns for Puget Sound and Washington Coastal escapement indicator stocks (Figure 2.5). Of the seven Puget Sound indicator stocks, the rate of change in escapement was significantly negative for Stillaguamish (-4.3\%) and Snohomish (-3.6\%) and significantly positive for Skagit spring (3.7\%). The remaining four Puget Sound indicator stocks (Nooksack Spring, Skagit summer/fall, Lake Washington, and Green River) showed no significant trends in escapement. However, due to widely varying escapements, there is considerable uncertainty around rate of change estimates for the Nooksack spring, Skagit summer/fall, and Green River stocks. Puget Sound indicator stocks have largely met their agency management objectives (i.e., exploitation rate ceilings) for the 1999-2018 time period, although these objectives have not been reviewed by the CTC. Of the nine Washington Coast indicator stocks, eight displayed no significant trends in escapement between 1999 and 2020. The rate of change in escapement was significantly negative for the Grays Harbor spring stock (-3.5\%). Six of the coastal indicator stocks have CTC-approved goals, which are usually met for fall (Quillayute, Hoh, Queets, Grays Harbor), but not spring/summer (Hoh, Queets) run timing groups. Five of the stocks-Hoko, Quillayute summer, Quillayute fall, Hoh spring/summer, and Grays Harbor fall—have wide Cls relative to other coastal indicator stocks. In the case of the Hoh and Queets spring/summer Chinook stocks, despite regularly missing goals and returning at levels consistently lower than observed historically, neither stock displayed a significant rate of change in escapement.

Figure 2.5-Long-term annual rates of change in escapements for Washington Chinook salmon stocks.

Note: Circles represent mean rate of change and bars represent 80\% Cls. The 2019 and 2020 Nooksack spring escapement estimates were not available to be included in this analysis.

### 2.2.5 Escapement Trends for Columbia River/Oregon Stocks

The escapement trends of those stocks examined from this geographic range are more variable than other area's stocks observed coastwide within the time period examined (1999-2020) (Figure 2.6). Of the nine stocks within this region, seven exhibit positive mean trends in escapement. The remaining two, the Siuslaw and Coquille stocks exhibit negative mean trends in escapement. The Coquille, while displaying a high degree of variability in escapement, displays the greatest rate of negative change out of all of those stocks examined by the CTC through return year 2020. The historically low escapements observed in the Coquille from 2018 through 2020 have spurred an investigation of potential causes and of expectations for this stock into the future, as indications of this stock's trajectory are dire.

Figure 2.6-Long-term annual rates of change in escapements for Columbia River/Oregon Chinook salmon stocks.

Note: Circles represent mean rate of change and bars represent 80\% CIs.

### 2.3 Profiles for Escapement Indicator Stocks

Escapements are graphed for stocks from Alaska, Canada, Puget Sound, Coastal Washington, Columbia River, and Oregon Coast regions. For each stock a commentary describes escapement methodology, escapement goal basis, escapement evaluation and agency comments. Escapement is usually reported as adult number by calendar year (CY). Escapement goals accepted by the CTC are shown as solid horizontal reference lines; escapement goals provided by the agencies are shown as dashed horizontal reference lines, which may change throughout the time series. Historical escapement and terminal run data are provided in Appendix B.

### 2.3.1 Southeast Alaska Stocks

Estimates for the three SEAK escapement indicator stocks are germane to large fish, defined as Chinook salmon $\geq 660 \mathrm{~mm}$ length mid-eye to tail fork (MEF) for the Situk and Unuk stocks or as fish $\geq$ age 1.3 for the Chilkat stock. Length-based estimates of large fish include mostly ocean-age-3, -4 , and -5 fish, and almost $100 \%$ of the females in the population, while excluding ocean-age-1 and -2 males. All SEAK indicator stocks produce primarily yearling smolt (freshwater-age1) except the Situk River, which produces around $90 \%$ subyearling (freshwater-age-0) smolt. Survey methods have been standardized since 1975 except for the Chilkat River, which was standardized in 1991 concurrent with the initiation of mark-recapture (MR) escapement estimation. Escapement estimates for the Unuk River are expanded aerial counts of large spawners. Biological escapement goals (BEGs) for each of these stocks have been reviewed and accepted by the CTC and consist of an S MSY $^{\text {point estimate and an escapement goal range. }}$

Based on CWT recoveries, SEAK stocks are classified into two categories of ocean migration patterns: inside rearing and outside-rearing. Inside-rearing stocks include those vulnerable to SEAK fisheries as immature fish, as well as mature, migrating fish, and include stocks returning
to the Chilkat and Unuk rivers. Outside-rearing stocks, sometimes referred to as "far north migrating stocks," have limited marine rearing time in SEAK and are harvested primarily during their spawning migrations through marine waters in the spring; this includes the stock returning to the Situk River.

In 1981, ADF\&G established a 15-year rebuilding program which included developing interim point escapement goals for all the SEAK stocks based on the highest observed escapement count prior to 1981. Since then, more rigorous escapement goal analyses have been adopted and used for management, based on the State of Alaska Policy for Statewide Salmon Escapement Goals and Policy for the Management of Sustainable Salmon Fisheries (Title 5 of the Alaska Administrative Code, Chapter 39, sections 222 and 223: 5 AAC 39.222 and 39.223).

### 2.3.1.1 Situk River

The Situk River is a non-glacial system near Yakutat, Alaska that supports an outside-rearing stock. Most harvest of Situk-origin Chinook salmon occurs in a commercial fishery, which operates in the estuary and nearby marine waters, and in sport and subsistence fisheries located in-river, in the estuary, and in nearby marine waters. These fisheries are prosecuted under a State of Alaska management plan (Situk-Ahrnklin Inlet and Lost River King Salmon Management Plan (5 AAC 30.365)) to achieve escapements within the escapement goal range. Calendar year exploitation rates averaged 9\%, ranging from 0\% to 29\% since 2011.

Escapement Methodology: The escapement is enumerated through a weir placed in the lower river; the escapement estimate subtracts sport and subsistence harvest that might occur above the weir. Sport harvest is estimated with a creel survey and a postseason mail-out survey and subsistence harvest is enumerated using a subsistence permit reporting program. The weir was operated from 1928 to 1955 and continuously since 1976 including escapement enumeration. Escapement estimates meet U.S. and bilateral CTC data standards.

Escapement Goal Basis: In 1991, ADF\&G revised the escapement goal to 600 large spawners (McPherson and Weiland 1991) ${ }^{2}$, and in 1997, the goal was revised to a range of 500 to 1,000 large spawners to conform to ADF\&G's escapement goal policy. The CTC reviewed and accepted this range in 1998. The analysis was updated by ADF\&G in 2003, leading to a proposed goal range of 450 to 1,050 , but this was not accepted by the CTC.

Escapement Evaluation: Productivity of the Situk River stock has generally been poor over the last decade, with annual escapements less than $85 \%$ of the lower bound of the goal occurring in five out of the last ten years. However, after a poor escapement of 420 fish in 2018, the 2019 and 2020 estimated escapements were 623 and 1,129 large Chinook salmon, well above the lower bound of the BEG. Like from 2015 through 2019, all terminal fisheries were closed in 2020 to allow as many fish as possible pass to escapement. There was also no harvest above the weir in 2020 and therefore an exact count of escapement was obtained (Figure 2.7).

[^2]Agency Comments: Total calendar year exploitation rates (all harvests within the PST area) averaged about $53 \%$ from 1990 to 2003. Because this stock has experienced poor production, exploitation rates have been substantially curtailed since 2004.

Figure 2.7-Situk River escapements of Chinook salmon, 1976-2020.

### 2.3.1.2 Chilkat River

The Chilkat River is a moderate-sized glacial system near Haines, Alaska, which supports an inside-rearing stock. Escapement estimates are germane to spawners that are ocean age-3 and older. Coded-wire tags have been applied to wild smolt at relatively high rates ( $8-10 \%$ ) beginning with the 1999 brood year; additional wild stock tagging occurred for three broods prior to that time. Relatively small terminal marine sport and subsistence fisheries target this stock. This stock is also caught in SEAK commercial troll, drift gillnet, and sport fisheries. Calendar year exploitation rates averaged $21 \%$ with a range of $2 \%$ to $42 \%$ since 2011.

Escapement Methodology: Escapements of large spawners have been estimated with a MR program annually since 1991 (Ericksen and McPherson 2004). Annual escapement estimates have an average coefficient of variation (CV) of about $14 \%$ since 1991, meeting the CTC bilateral data standard. From 1975 to 1992, aerial survey counts were conducted on two small tributaries with relatively clear water and results from these estimates were inconsistent with radio telemetry studies conducted in 1991 and 1992. The studies found that these two tributaries represented less than $5 \%$ of the total escapement and as a result, aerial surveys were discontinued.

Escapement Goal Basis: An initial 1981 escapement goal was 2,000 large fish, based on an assumed fraction of the total escapement represented by aerial survey counts. A revised escapement goal range of 1,750 to 3,500 large spawners, based on MR estimates of
escapement and limited CWT information (Ericksen and McPherson 2004) was reviewed and accepted by the CTC in 2004.

Escapement Evaluation: Escapements to the Chilkat River were $\geq 85 \%$ of the goal in all years except 2007 and from 2016 to 2018. The 2019 and 2020 escapement estimates of 2,028 and 3,180 large fish, respectively, were each above the lower bound of the escapement goal range, rebounding from an all-time low estimate of 873 fish in 2018 (Figure 2.8).

Agency Comments: Like other Chinook salmon stocks in Alaska, the Chilkat stock has been experiencing a decline in productivity and restrictive management measures that have been in place since 2018 will continue in 2021.

Figure 2.8-Chilkat River escapements of Chinook salmon, 1991-2020.

### 2.3.1.3 Unuk River

The Unuk River is a moderate-sized glacial system that flows into Behm Canal northeast of Ketchikan, Alaska, which supports an inside-rearing stock. Coded-wire tags have been applied to wild smolt at relatively high rates ( $7-10 \%$ ) beginning with the 1992 brood year. Harvest of immature and mature fish occurs predominately in SEAK commercial and sport fisheries, although some fish are also caught in NBC commercial net and troll fisheries. Calendar year exploitation rates averaged 43\% with a range of $18 \%$ to $73 \%$ since 2011.

Escapement Methodology: Escapements of large spawners were derived from MR estimates of total escapement from 1997 to 2011, and from expanded survey counts from 1977 to 1996 and 2012 to present. Radio telemetry studies in 1994 and 2007 demonstrated that survey area coverage includes approximately $80 \%$ of the spawning population; the expansion factor for survey counts is 4.83 (Hendrich et al. 2008). From 1997 to 2011, CVs of the MR escapement estimates averaged $11 \%$ and were less than $15 \%$ in all but one year (2011). The average CV is
$12 \%$ for expanded survey counts performed since 2012 and thus meet bilateral CTC data standards.

Escapement Goal Basis: In 1994, ADF\&G revised the Unuk River escapement goal to 875 large spawners observed during survey (index) counts (unpublished work), which the CTC reviewed and accepted. In 1997, ADF\&G revised the goal to a range of 650 to 1,400 large spawners observed during index counts (McPherson and Carlile 1997), which the CTC reviewed and accepted in 1998. Since the expansion factor for surveys was unknown at that time, the goal was expressed as an index peak survey count. In 2008, a more extensive analysis was completed using the 1982 to 2001 brood years with spawners, recruitment, and fishing mortality expressed in total numbers of fish (Hendrich et al. 2008). In 2009, the CTC accepted a BEG range of 1,800 to 3,800 large spawners, with a point estimate of 2,764 fish.

Escapement Evaluation: The Unuk River stock had annual escapements from 1977 to 2011 that were within or above the escapement goal range. However, productivity of the Unuk River stock has been poor over the last decade with annual escapements less than $85 \%$ of the lower bound of the goal occurring in five of the last ten years. Escapements were above the lower bound of the BEG in 2018 and 2019; however, the 2020 estimated escapement was 1,135 (CV=0.13), well below the lower bound of the BEG (Figure 2.9).

Agency Comments: The large reduction in run strength of the Unuk River stock in recent years was unexpected given its history of consistent production. There are no directed fisheries that target this stock; sport fishing in fresh water is closed, marine sport fishing in East Behm Canal is closed during the spring and summer, and commercial fishing in nearby marine waters in upper Behm Canal is closed. Additional management measures have been in place since 2014 to limit harvest of this stock in SEAK fisheries and restrictions will continue in 2021.

Figure 2.9-Unuk River escapements of Chinook salmon, 1977-2020.

### 2.3.2 Transboundary River Stocks

The transboundary (TBR) stocks include Chinook salmon returning to the Alsek, Taku, and Stikine rivers. Escapement estimates in the Alsek River are for ocean age-2 fish and older. Escapement estimates in the Taku and Stikine rivers are for large fish only, defined as Chinook salmon $\geq 660 \mathrm{~mm}$ length mid-eye to tail fork, and include ocean age-3 through age-5 fish, which contain almost $100 \%$ of the females in the population. Survey methods have been standardized since 1973 in the Taku River, since 1975 in the Alsek and Stikine rivers, and BEGs exist for each of these stocks.

All three TBR stocks are classified as outside rearing based on marine CWT recovery patterns. These stocks emigrate as yearling smolt and have limited marine rearing in SEAK waters; therefore, they are harvested primarily during their spawning migrations each spring.
In response to low abundance, a 15-year rebuilding program was established in 1981 (ADF\&G 1981). Concurrently, ADF\&G established interim escapement goals for all three stocks, based on the highest observed escapement count prior to 1981. Escapement goals for all three TBR stocks have subsequently been revised by ADF\&G and DFO, and have been reviewed and accepted by the CTC, Canadian Centre for Science Advice Pacific (CSAP), and the TBR Panel. Escapement goal ranges are used by ADF\&G for domestic management, as described in the State of Alaska Policy for Statewide Salmon Escapement Goals and Policy for the Management of Sustainable Salmon Fisheries. Escapement goal ranges are also used by the U.S. and Canada for implementation of Annex IV, Chapter 1 of the PST.

### 2.3.2.1 Alsek River

The Alsek River is a large glacial system that originates in Southwest Yukon Territory and Northwest British Columbia, Canada, and flows into the Gulf of Alaska about 50 miles east of Yakutat, Alaska. This river supports a run of outside-rearing Chinook salmon.

Escapement Methodology: Since 1976, escapements have been monitored using a weir on the Klukshu River, one of 51 tributaries of the Tatshenshini River, the principal salmon-producing tributary of the Alsek River. Counts of returning ocean age-2 and older Chinook have been collected from 1976 to present. Concurrent with the weir counts, Alsek River drainage-wide MR escapement estimates were generated from 1998 to 2004 through a cooperative effort among the Champagne and Aishihik First Nations, DFO, and ADF\&G. An expansion factor of 4.0 is used to convert the Klukshu River inriver run (weir count plus any below-weir harvest) to Alsek River above border drainage-wide inriver run estimates. Total drainage-wide inriver run is estimated by adding the above border inriver run plus any U.S. harvests. Assessments using the expansion factor had a CV of $35 \%$ (Bernard and Jones 2010), failing to meet bilateral CTC data standards (CTC 2013).

Escapement Goal Basis: Spawner-recruit analysis in 2010 resulted in a recommended BEG of 3,500 to 5,300 ocean age-2 and older Chinook salmon which was reviewed and accepted by the CTC, ADF\&G, CSAP and the TBR Panel (Bernard and Jones 2010). The previous goal was based solely on the Klukshu River return (McPherson et al. 1998).

Escapement Evaluation: Annual escapements of less than 85\% of the lower bound of the current goal range have been observed four times since 1976, and all have occurred in the last

15 years (2006, 2008, 2016 and 2017). Beginning in 2018, escapement estimates have been well above the lower bound of the BEG; the 2020 escapement estimate is $5,330 \geq$ ocean age- 2 Chinook salmon (Figure 2.10).

Agency Comments: Most harvest of Alsek-origin Chinook salmon occurs in the U.S. commercial fishery in Dry Bay and in Aboriginal fisheries in the upper watershed in Canada. Some fish are also harvested in sport fisheries in each country. Calendar year exploitation rates averaged $9 \%$ with a range of $1 \%$ to $25 \%$ since 2011.

Figure 2.10-Alsek River escapements of Chinook salmon, 1976-2020.

### 2.3.2.2 Taku River

The Taku River is a large glacial system that originates in Northwest British Columbia, flows into marine waters of SEAK near Juneau, Alaska, and supports a run of outside-rearing Chinook salmon. Most Taku River Chinook salmon are caught in terminal marine waters of SEAK and in the lower Taku River in Canada. Directed gillnet fisheries take place in terminal U.S. (District 111 of SEAK) and Canadian inriver fisheries when forecasted abundance or in-season assessments exceed predetermined levels as described in the 2019 PST Agreement under Annex IV, Chapter 1, Transboundary Rivers 3(b)(3). Taku River Chinook are incidentally harvested in terminal directed sockeye salmon gillnet fisheries, sport fisheries near Juneau, Alaska, and inriver in Aboriginal and sport fisheries in Canada and in a U.S. personal use fishery just below the border. Taku Chinook salmon are also harvested outside of the terminal area, primarily in SEAK sport and troll fisheries.

Escapement Methodology: Escapement estimates of large Chinook salmon have been generated using MR experiments in 1989, 1990, 1995 to 1997, 1999 to 2010, and 2014 to 2019. Standardized aerial survey counts have been performed by ADF\&G since 1973. Counts
prior to 1989, from 1991 to 1994, 1998, and 2011 to 2013 were expanded by a factor of 5.2, which is the average of the ratio of the MR estimates to aerial survey counts. Escapement estimates based upon expanded aerial survey counts are assumed to be unbiased and have a CV of about 30\% (McPherson et al. 2010) which do not meet CTC data standards (CTC 2013). The MR estimates are from cooperative stock assessment efforts among the Taku River Tlingit First Nation, DFO, and ADF\&G. Since 1995, MR escapement estimates had an average CV of $15 \%$, ranging from $9 \%$ to $38 \%$, and most assessments met bilateral CTC data standards.

Escapement Goal Basis: Prior to 1999, several drainage-wide or index goals were developed by the U.S. and Canada using limited data. A BEG based upon maximizing smolt production was accepted by the CTC and used for management from 1999 to 2009 (McPherson et al. 2000). Spawner-recruit analysis in 2009 resulted in a recommended BEG of 19,000 to 36,000 large Chinook salmon which was reviewed and accepted by the CTC, ADF\&G, CSAP and the TBR Panel (McPherson et al. 2010).

Escapement Evaluation: Escapements of less than $85 \%$ of the lower bound of the current goal range occurred eight times since 1975 and most notably in each of the last 5 years. The 2020 escapement estimate is $15,593(C V=0.20)$ large Chinook salmon, which is below the $85 \%$ threshold of the lower bound of the escapement goal range and less than half of the $\mathrm{S}_{\text {MSY }}$ point goal of 25,500 (Figure 2.11).

Agency Comments: Like the Stikine River stock of Chinook salmon and other SEAK stocks, the Taku River stock has been experiencing a decline in productivity, largely due to poor marine survival. Restrictive management measures have been in place since 2018 and will continue in 2021. Until marine survival improves, it is unlikely that productivity will improve enough to allow directed fisheries. Calendar year exploitation rates averaged $19 \%$ with a range of $1 \%$ to 34\% since 2011.

Figure 2.11-Taku River escapements of Chinook salmon, 1975-2020.

### 2.3.2.3 Stikine River

The Stikine River drainage is the largest in SEAK, originating in British Columbia and flowing into the marine waters in central SEAK near the towns of Petersburg and Wrangell. The Stikine River supports a run of outside-rearing Chinook salmon and most harvest occurs in terminal areas, including U.S. commercial gillnet and sport fisheries in District 108 near Petersburg and Wrangell. There are commercial gillnet, Aboriginal, and recreational fisheries in the Canadian portion of the drainage. Stikine Chinook salmon are also harvested outside of the terminal areas in SEAK sport and troll fisheries. Starting in 2005, during years of surplus production to the Stikine River, directed Chinook salmon fisheries were allowed in District 108 marine waters and inriver in Canada.

Escapement Methodology: From 1975 to 1984, index escapement estimates were generated using survey counts performed by ADF\&G, and since 1985, counts were made through a weir on the Little Tahltan River operated by DFO and the Tahltan First Nation. Since 1996, MR studies were conducted annually to estimate total escapement. The MR estimates are cooperative stock assessment efforts among the Tahltan First Nation, DFO, and ADF\&G. Combined, these efforts indicated weir counts represented $17 \%$ to $20 \%$ of the total escapement (Pahlke and Etherton 1999). Since 1996, the MR escapement estimates had an average CV of $16 \%$, ranging from $7 \%$ to $35 \%$, about half of which met bilateral CTC data standards (CTC 2013).

Escapement Goal Basis: Spawner-recruit analysis in 1999 resulted in a recommended BEG of 14,000 to 28,000 large Chinook salmon, which was reviewed and accepted by the CTC, ADF\&G, CSAP and the TBR Panel (Bernard et al. 2000). Previously, several drainage-wide or index goals were developed by the U.S. and Canada and were based on limited data.

Escapement Evaluation: Escapements of less than $85 \%$ of the lower bound of the current goal range occurred nine times since 1975 and most notably in 4 of the last 5 years. The 2020 escapement estimate is 9,753 (CV=0.21) large Chinook salmon, which is below the $85 \%$ threshold of the lower bound of the escapement goal range (Figure 2.12).

Agency Comments: Like the Taku River stock of Chinook salmon and other SEAK stocks, the Stikine River stock has been experiencing a decline in productivity, largely due to poor marine survival. Restrictive management measures have been in place since 2018 and will continue in 2021. Until marine survival improves, it is unlikely that productivity will improve enough to allow directed fisheries. Calendar year exploitation rates averaged $26 \%$ with a range of $2 \%$ to $38 \%$ since 2011.

Figure 2.12-Stikine River escapements of Chinook salmon, 1975-2020.

### 2.3.3 Canadian Stocks

Since the beginning of the Chinook salmon rebuilding program of the 1985 PST Agreement, escapement goals for Canadian Chinook salmon stocks were generally based on doubling the average escapements recorded from 1979 to 1982. The doubling was based on the premise that Canadian Chinook salmon stocks were overfished and that doubling the escapement would still be less than the optimal escapement estimated for the aggregate of all Canadian Chinook salmon populations (PSC 1991). Doubling was also expected to be a large enough change in escapements to allow detection of the change in numbers of spawners and the subsequent production. The escapement goals of most Canadian stocks are currently being reviewed; two stocks (Harrison and Cowichan) have PSC-agreed escapement goals.

### 2.3.3.1 Northern British Columbia

### 2.3.3.1.1 Nass River

The Nass River is the largest river in Area 3, draining an area of approximately $18,000 \mathrm{~km}^{2}$. It flows southwest from the interior of British Columbia into Portland Inlet and the estuary is located 30 km south of the Alaska/British Columbia border. The Nass River is constrained by a canyon at Gitwinksihlkw (GW) that was formed by the Tseax Volcano in 1775 and is approximately 40 km upstream from the estuary. The mainstem of the Nass River is extremely turbid with visibility near zero for most of the year. Among the major Chinook salmon producing tributaries, the Bell Irving River is glacially turbid while the Meziadin, Cranberry/Kiteen, Kwinageese and Damdochax rivers are relatively clear. The Nass River Chinook salmon stock is primarily (97\%) stream-type and are far north migrating.

Escapement Methodology: Prior to 1992, DFO observations of Nass River Chinook salmon escapement were based on visual counts. Programs using MR have been conducted since 1992 by Nisga'a Fisheries to estimate total spawning escapement in the Nass River. The Nass MR program uses two fish wheels at GW in the Lower Nass River canyon and occasionally two fish wheels at Grease Harbor further upstream to capture fish for tag application. The Meziadin River fishway, a weir across the Kwinageese River, and a dead pitch program on the Damdochax River are used for tag recovery. Tags were also recovered in upriver fisheries and on the spawning grounds. A modified Petersen model was used to estimate the total population of Chinook salmon past the tagging location. Spawning escapements were calculated as the estimated population past GW from the MR studies, minus upriver catches in sport and First Nations fisheries. These MR methods are currently under review. Three tributaries with Chinook salmon populations-the Kincolith, Ishkeenickh and the Iknouk—enter the Nass River below GW. Visual estimates of Chinook salmon in these systems were augmented using fence counts on the Kincolith River in 2001, 2002, 2005, and 2007 to estimate escapements below the fish wheels.

Escapement Goal Basis: There is no PSC-agreed escapement goal for the Nass River aggregate of Chinook salmon. The Fisheries Operational Guidelines define two goals for managing Chinook salmon fisheries: an operational escapement target of 20,000 fish and a minimum escapement target of 10,000 fish. If escapements are projected to be below 10,000 fish, then no fishing on Nass River Chinook salmon would be recommended. The median estimate of $\mathrm{S}_{\mathrm{MSY}}$ upstream of GW using the habitat model was 16,422 (CV $=23 \%$ ) Chinook salmon based on a watershed area of $15,244 \mathrm{~km}^{2}$ (Parken et al. 2006; Figure 2.13). The 2020 escapement estimate for the Nass River above GW was 12,868 (CV=0.08) fish, which is below the escapement goal (Appendix Table B3; Figure 2.13).

Agency Comments: Chinook salmon escapement estimates produced before 1992 have been calibrated to the MR estimates. The Sentinel Stocks Program (SSP) and Northern Endowment Fund have funded projects on the Kwinageese River and Damdochax Creek designed to increase recoveries and improve the escapement estimates for the Nass River aggregate of Chinook salmon.

Figure 2.13-Nass River escapements of Chinook salmon, 1977-2020.

### 2.3.3.1.2 Skeena River

The Skeena River is the second largest river in British Columbia and drains an area of approximately $54,400 \mathrm{~km}^{2}$. It supports the second largest aggregate of Chinook salmon stocks in British Columbia with over 75 separate spawning populations. There are four large lakestabilized tributaries, Kitsumkalum, Morice, Babine and Bear rivers, and genetics studies show escapements in these areas typically account for $63 \%$ of the total abundance in the Skeena River. The Kitsumkalum River is glacially turbid and visual counts of salmon are not possible. In contrast, the Morice, Bear, Babine, and Kispiox tributaries are relatively clear, especially in late summer when most of the Chinook salmon spawning occurs, allowing for visual counts. Skeena River Chinook salmon are primarily stream-type salmon (97\%) and are far north migrating. Most of the Skeena River Chinook salmon populations are summer run but spring run fish occur in the Cedar and Upper Bulkley rivers.

Escapement Methodology: Most of the escapement estimates are based on visual counts made during helicopter, fixed-wing aircraft and/or from stream walking surveys, but counts also occur at weirs across the Babine, Sustut, and Kitwanga rivers. The Kitsumkalum River is the exploitation rate indicator stock for Northern British Columbia, and the spawning population has been estimated using a MR program since 1984. The Skeena multi-method escapement index is the sum of Chinook salmon enumerated using various methods on each system. The Kitsumkalum stock represents approximately $30 \%$ of the spawners measured by the Skeena escapement index. The Bear and Morice river populations have contributed 20\% and 26\%, respectively, to the escapement index since 1984. The Bear and Morice populations account for $46 \%$ of the Skeena multi-method escapement index which overestimates their contribution when compared to genetic-based estimates.

Chinook salmon runs to the Skeena River have also been estimated using the proportion of Kitsumkalum River fish measured from genetic samples collected at the Tyee test fishery and from Kitsumkalum River Chinook salmon escapement estimates from independent MR
programs (Figure 2.14, checkered bars). Preliminary estimates are available from 1984 to 2020 as a result of Sentinel Stocks Program and Northern Endowment Fund projects. The geneticbased estimates represent an improvement over the historic indices because they include measures of uncertainty. Also, comparisons between years are valid since the method is consistent across the time series, whereas methods used for the historic indices varied through time.

The genetic studies found that the Kitsumkalum River conservation unit (CU) contributes, on average, $18 \%$ to the Skeena River aggregate. The Morice, Bear and Babine populations make up the Skeena Large Lake conservation unit and contribute 31\%, $7 \%$ and $7 \%$ to the aggregate, respectively. An average contribution of $45 \%$ makes the Skeena Large Lake conservation unit the largest in the watershed. The estimated 2020 escapement for the Skeena River aggregate was 13,386 fish using the historic index and 16,243 (CV=0.21) fish using the genetic-based estimate (Appendix Table B3; Figure 2.14).

Escapement Goal Basis: There is no CTC-agreed escapement goal for the Skeena River aggregate of Chinook salmon. The estimate of $\mathrm{S}_{\text {MSy }}$ for the Kitsumkalum indicator stock is 8,621 Chinook salmon based on stock-recruitment analyses (McNicol 1999; updated in Parken et al. 2006). Habitat-based estimates of $S_{\text {MSY }}$ and other reference points are available for stocks within the Skeena River, but estimates of total escapement (or calibration of the visual indices) are needed to make them effective (Parken et al. 2006). Future assessments will partition this large aggregate into stocks by run timing, life history and geographic areas.

Agency Comments: Terminal fisheries in the Skeena River include commercial gillnet in the terminal exclusion area (River Gap Slough, Area 4), inriver sport and Aboriginal fisheries. Estimates of inriver sport catch were only included in the total terminal run estimates when data were available from creel surveys. Creel surveys were conducted on the Lower Skeena River below Terrace in 2003 and from 2010 to 2017. The inriver sport fishery was closed in 2018 and was limited in 2019 and 2020 by management actions to protect sockeye salmon. Spawning escapements to the Kitsumkalum River exceeded S MSY in every year except 1998 and 2017 (Figure 2.15).

Figure 2.14-Skeena River escapements of Chinook salmon, 1975-2020.

Figure 2.15-Kitsumkalum River escapements of Chinook salmon, 1984-2020.

### 2.3.3.2 Central British Columbia

### 2.3.3.2.1 Rivers Inlet

The Rivers Inlet aggregate of Chinook salmon is monitored using an index of escapements to the Wannock, Kilbella and Chuckwalla rivers. The Wannock River drains Owikeno Lake into the head of Rivers Inlet. It is about 6 km long, over 100 m wide, and is glacially turbid. Wannock

Chinook salmon are genetically distinct from other Chinook salmon populations from the central coast of British Columbia. This ocean-type stock exhibits fall run timing and is renowned for its large body size, due to high proportions of ocean age-4 and age-5 year components in the return. The Kilbella and Chuckwalla river systems share an estuary on the north shore of Rivers Inlet. These systems are relatively small and run clear, but the degree of turbidity fluctuates with seasonal precipitation. The Chinook salmon populations in the Chuckwalla and Kilbella rivers have summer run timing and are stream-type salmon. The largest contributor to the index is the Wannock River, which represents an average of $76 \%$ of the production for this index over the past decade, and over $95 \%$ since 2010. Since 2016, environmental conditions and limited resources have precluded direct estimates of escapement to the Wannock, Kilbella and Chuckwalla rivers. Covariation analysis and regressions involving robust escapement estimates for Atnarko Chinook salmon have been used to infill escapement estimates in the Wannock River, 2016 to 2020, and Chuckwalla and Kilbella rivers, 2018 to 2020 (Appendix Table B3; Figure 2.16). In 2020, indirect Chinook escapement estimates were 3,596 fish for the Wannock River and 831 fish for Chuckwalla and Kilbella rivers.

Escapement Methodology: Chinook salmon escapement estimates for the Wannock stock are produced from an annual carcass recovery program which was not conducted in 2020. Estimates were derived by expanding the number of carcasses pitched using historical recovery rates. Expansion factors are somewhat subjective and take into consideration water clarity, river height, and recovery effort. Programs to calibrate carcass recoveries with population estimates from MR experiments were conducted from 1991 to 1994 and again in 2000. Results suggest the estimates based on the subjective expansions of carcass recoveries may underestimate the Wannock Chinook salmon population. Inherent biases typical in carcass recovery programs as well as imprecision in the MR estimates leads to uncertainty in calibration of the carcass estimates.

Chinook salmon escapements in the Chuckwalla and Kilbella rivers are estimated using Area Under the Curve (AUC) methods applied to visual counts from helicopter surveys. Typically four flights are made during the spawning period.

Escapement Goal Basis: There are no PSC-agreed escapement goals for the Rivers Inlet aggregate of Chinook salmon. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available but estimates of total escapement are needed to apply them. Habitat-based escapement goals may overestimate $\mathrm{S}_{\text {MSY }}$ for the Wannock stock because the river has a relatively small amount of available spawning area (Parken et al. 2006).

Agency Comments: A hatchery enhancement program occurs on the Wannock River but the contribution to the total population is unknown. Production from enhancement of the Kilbella and Chuckwalla rivers from 1990 to 1998 is thought to have had significant influence on escapements from 1994 to 2003 but estimates of the enhanced component are not available. However, estimated returns to the Kilbella and Chuckwalla rivers averaged 1,300 Chinook salmon during the period of enhancement. Recent runs have averaged less than 500 Chinook salmon for both rivers combined. It is unclear if these populations have returned to preenhancement levels or are simply experiencing a period of poor production, similar to SEAK stocks just to the north.

Figure 2.16-Rivers Inlet escapement index of Chinook salmon, 1975-2020, including Wannock River (upper) and Kilbella and Chuckwalla rivers (lower).

### 2.3.3.2.2 Atnarko River

The Atnarko River feeds the Bella Coola River and is situated in Statistical Area 8 on the Central Coast of British Columbia. Chinook salmon spawning in this river are predominantly ocean-type but stream-type Chinook are also observed. This constitutes the largest complex of Chinook salmon in Central British Columbia. Hatchery releases of Atnarko Chinook salmon have averaged around 2 million annually with recent CWT releases in excess of 400,000 fish. Atnarko CWT recoveries occur in both U.S. and Canadian AABM fisheries as well as coastal British Columbia ISBM fisheries.

Following the 2009 PST Agreement, the CWT Improvement Program highlighted the lack of a Chinook salmon indicator in the Central British Columbia region. In order to convert the existing Atnarko Chinook Assessment program into an exploitation rate indicator, a series of objectives were identified including the application of 250,000 additional CWTs, sampling of the terminal
commercial, sport, and First Nations fisheries, and reintroduction of an MR program to improve escapement estimates (Vélez -Espino et al. 2011). Implementation of these changes began in 2009 (Vélez -Espino et al. 2010) and subsequent MR programs have yielded escapement estimates with corresponding CVs of less than $15 \%$ for all years (Vélez -Espino et al. 2014). The estimated total escapement in the Atnarko River in 2020 (excluding jacks) was 19,176 (CV = 0.091 ) fish with a wild escapement of 9,835 (CV=0.096) fish (Appendix Table B3; Figure 2.17). The wild escapement for 2020 was above the agency escapement goal of 5,009 fish.

Escapement Methodology: Three methods have been used since 1990 to generate independent estimates of Chinook salmon escapement in the Atnarko River. These methods are based on (1) CPUE during broodstock collection, (2) carcass counts during dead pitching, and (3) the number of spawners observed during drift boat surveys. The simplicity and low cost of these three methods has allowed the continuous monitoring of Atnarko River escapement, and the average of these three population estimates (3MA method) has been used as escapement estimates in years without MR studies. A serious flood event in the fall of 2010 impacted the Atnarko River by altering flow dynamics and creating a sequence of obstructive log jams. As a result, the use of rafts to obtain drift counts was no longer feasible. Robust maximum likelihood estimates within a model selection framework have been developed for escapement of total and wild Atnarko Chinook salmon, based on MR data for years 2001 to 2003 and 2009 to 2020. Escapement estimates for years without MR studies were calibrated using Generalized Linear Models based on these high-quality MR escapement estimates and data routinely collected for the 3MA method (Vélez-Espino et al. 2014). The estimation model used for time series calibration also serves as a tool to generate reliable escapement estimates based on broodstock CPUE and carcass counts. The calibrated escapement estimates have yielded escapement estimates with corresponding CVs of less than 15\% for all years, except 1995 (17.9\%) and 2006 (15.6\%; Velez-Espino et al. 2014), and most assessments met bilateral CTC data standards.

Escapement Goal Basis: An agency goal of 5,009 wild fish was developed using a habitat-based approach (Parken et al. 2006; Vélez-Espino et al. 2014). This escapement goal was accepted by the PSC and appears in Attachment I of Chapter 3 of the 2019 PST Agreement, but it has not been reviewed by the CTC.
Agency Comments: The Atnarko River has been developed as an exploitation rate indicator stock (Vélez-Espino et al. 2011) and MR estimates with corresponding CVs less than $15 \%$ have been attained in all years (2001-2003 and 2009-2020), achieving bilateral data standards. The estimation model used for the 1990 to 2013 time series calibration can also generate reliable escapement estimates based on broodstock CPUE and carcass counts. In future years when MR data are absent, carcass counts used with a calibrated time series of escapement provide a method to produce escapement estimates. Future calibrations would be required for years without MR data and will include new data derived from subsequent MR studies. This was not necessary for 2020 because MR studies took place for Atnarko Chinook salmon.

Figure 2.17-Atnarko River escapements of wild adult (excluding jacks) and total adult (hatchery and wild, excluding jacks) Chinook salmon, 1990-2020.

### 2.3.3.3 West Coast Vancouver Island and Strait of Georgia

### 2.3.3.3.1 West Coast Vancouver Island

Escapement Methodology: Under the 2019 PST Agreement, two escapement indices are reported to represent escapement to systems with little or no hatchery influence in Northwest Vancouver Island (NWVI) and Southwest Vancouver Island (SWVI) areas. The NWVI aggregate represents the sum of the total escapements for four rivers (Colonial-Cayeagle, Tashish, Artlish, and Kaouk), and the SWVI aggregate represents the sum of the total escapement for three rivers (Bedwell-Ursus, Megin, and Moyeha). These systems were chosen to provide an index of escapement for wild WCVI stocks in general based on historical consistency of high-quality data. However, the escapement methodology changed in 1995 and earlier estimates have not been calibrated to the new methodology. DFO also developed a 14-stream expanded index (Figure 2.18), which includes escapements to the NWVI and SWVI indices plus the following WCVI streams: Marble (Area 27); Leiner, Burman, and Tahsis (Area 25); Sarita, Nahmint (Area 23); and San Juan (Area 21). An MR program in the Burman River was conducted from 2006 to 2018 in addition to the regular Area Under the Curve (AUC) methodology based on swim and foot surveys. Robust estimation of escapement using open-population models within a model selection framework (see Vélez -Espino et al. 2016) started in 2009. In 2019 and 2020, discounted survey life (DSL) was used. DSL is drawn from the relationship established from 2009-2018 between raw AUC fish-days divided by the mark-recapture population size to provide an index of spawning area residence time. These DSL data were regressed against the timing of the first freshet as days from September 1. See relationship of DSL and days from freshet starting from September $1^{\text {st }}$ for the Burman River (Figure 2.20). With no mark-recapture
and establishing that relationship, the annual DSL index is now drawn using the date of the first freshet to provide the indexed residence time in the spawning area that is used to divide the raw AUC fish-day estimate to determine escapement. In 2020, the freshet occurred on September 23 suggesting a DSL of 12.3 days. A comparison of these escapement estimates with those produced by the AUC method is shown in Figure 2.19. For consistency between aggregate components, the Burman River escapement estimate used for the 14 -stream index is based on the swim and foot survey method instead of the MR or DSL estimates. The escapement indices in 2020 were 1,416 Chinook salmon for NWVI index, 442 Chinook salmon for the SWVI index and 19,273 for the 14-stream index (Appendix Table B5; Figure 2.18).
Over the last decade, the PSC Sentinel Stocks Program and Endowment Fund programs funded several studies aimed at producing high quality escapement estimates that are consistent with the CTC data quality standards (CTC 2013). In 2013 and 2014, Canadian Science Advisory Secretariat process workshops were held with the objective of evaluating the escapement estimation methodology used to assess the abundance of WCVI indicator stocks. The reviews produced several recommendations for further work and potential improvements. It is anticipated that this work may eventually result in revised escapement data, with measures of precision, which are better quality than the estimates presented in Figure 2.19.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock group.
Agency Comments: Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for these stocks (Parken et al. 2006), however estimates of total escapement are needed to make them effective. Escapements have remained low in nonenhanced streams since 1999 despite terminal fishing restrictions in effect in Areas 24-26 from July to September each year. Escapement indices to all non-enhanced Clayoquot Sound and Kyuquot Sound Chinook salmon streams remain below 500 fish.

Figure 2.18-WCVI 14-stream (top), SWVI 3-stream (middle) and NWVI 4-stream (bottom) indices of escapement of Chinook salmon, 1975-2020.
Note: The escapement methodology changed for all WCVI index streams in 1995 (indicated by the vertical red line) and prior estimates have not been calibrated to the new methodology.

Figure 2.19-Burman River Chinook escapement based on Petersen estimates from the Sentinel Stock Committee (2006-2013), area under the curve (AUC)-based agency estimates (20062018), open-population mark-recapture estimates (MR; 2009-2018), and discounted survey life (DSL; 2019-2020). Bars are 95\% Cls.

Figure 2.20-Burman River Chinook DSL estimates from days to freshet from September 1 using a Bayesian non-linear model fit to the data.

### 2.3.3.3.2 Upper Strait of Georgia

Under the 2019 PST Agreement, two escapement indicators are identified within the Upper Strait of Georgia. Phillips River fall Chinook salmon is an enhanced escapement indicator for the mainland inlets area, and a yet to be determined system will represent the Northeast Vancouver Island (NEVI) area. Work is ongoing to identify the most suitable escapement indicator for the NEVI area, which is not reported on this year.

The estimated escapement for Phillips River, representing the mainland inlets portion of the Upper Strait of Georgia stock group was 3,330 in 2020 (Appendix Table B4; Figure 2.21).

Escapement Methodology: The accuracy of most escapement estimates for the mainland inlet systems is likely poor, due to low visibility of glacial systems, remote access, and timing of surveys. Furthermore, these escapement estimates have been based primarily on aerial counts targeting other salmon species, which may not coincide with the main spawning period for Chinook salmon. Escapement estimates for these systems have been reported since 1975.

In 2009, an MR program (Live Tag/Deadpitch) was initiated; historically, Phillips Chinook were assessed by helicopter, bank walks and swim surveys. Between 2001-2011, estimation methods utilized were AUC or Peak Live + Dead. Since 2012, escapement estimates have been based on MR results, derived by a modified Petersen estimator (Chapman formula). Over the 2012-2019 period, program precision (CV) has averaged 18.5\%. Broodstock and other removals are also included in the total return as Phillips Chinook have been enhanced since 1988. Over that time juvenile releases have been coded-wire tagged to varying degrees. The 2019 brood will be the final enhanced release of Phillips Chinook; MR assessment will continue.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock group.
Agency Comments: Assessment of stock status is highly uncertain and the escapement time series requires standardization to better represent this stock group in the PSC Chinook Model. Differences in ocean distributions, run timing, and life history indicate that future assessments should separate the stock group into conservation units to better represent differences in population dynamics and both freshwater and smolt survival.

Figure 2.21-Phillips River escapements of Chinook salmon, 1975-2020.
Note: Since 2012, the escapement estimates have been derived through an intensive MR program, as indicated by the red vertical line. Prior to that, escapement estimates were based on a variety of visual surveys. No calibration between the pre- and post-2012 methods have been made.

### 2.3.3.3.3 Lower Strait of Georgia

The Lower Strait of Georgia rivers monitored for naturally spawning fall Chinook salmon escapement are the Cowichan and Nanaimo rivers (Figure 2.22 and Figure 2.23). The estimated escapement in 2020 was 10,129 adult Chinook salmon for the Cowichan River ( 8,737 natural spawners) and 2,970 for the Nanaimo River (Appendix Table B4).

Escapement Methodology: Total Chinook salmon returns have been estimated since 1975. Prior to 1988, escapement estimates from the Cowichan River were derived from swim and aerial surveys. This approach was also used for the Nanaimo River prior to 1995. Since 1988, a counting fence has been operated on the lower Cowichan River. Between 1995 and 2003, a counting fence and carcass MR surveys were used in the Nanaimo River, and since 2004, AUC snorkel survey methods have been used. Survey life utilized in AUC estimate methodology is based on a tagging study completed in 2006.

Cowichan River fence operations rarely span the entirety of the fall Chinook migration due to rainfall driven flow increases exceeding operational limits. As a result, the proportion of the natural spawning population enumerated at the fence varies between years. Expansion methods to achieve a population estimate have included snorkel surveys, carcass markrecapture and generalized run timing curves. A PIT tag-based method has been used since 2017 to produce a Peterson estimate. This project is a part of a five-year project that has been funded by the Pacific Salmon Commission Endowment Fund programs to investigate alternative escapement methods for Cowichan River Chinook salmon. Raw and expanded Chinook salmon counts are shown in Figure 2.24.

Escapement Goal Basis: An escapement goal of 6,500 (CV = 33\%) for the Cowichan River was accepted by the CTC in 2005 (Tompkins et al. 2005). There is currently no PSC-agreed
escapement goal for the Nanaimo River; however, there is a habitat-based estimate for SmSY of 3,000 spawners (median; CV = 14\%; Parken et al. 2006).

Agency Comments: The Cowichan River stock showed considerable increases in escapement in 1995 and 1996, followed by a rapid decline to conservation concern levels of more than 15\% below the escapement goal. Significant Canadian fishery management actions were used to reduce exploitation levels on the Lower Strait of Georgia natural stock group. Following a low point in 2009, the population has shown a strong rebuilding trend driven mainly by natural origin Chinook prompting relaxation of several area-specific marine closures Hatchery production has been reduced from a peak of 3 M to 650 K smolts and hatchery-origin fish currently contribute approximately $10 \%$ of the natural spawning population. A large-scale habitat restoration project conducted in 2006 at Stoltz Bluff significantly reduced fine sediment inputs to the lower 25 km . Considerable focus has also been put on water management in recent years.

### 2.3.3.4 Fraser River Stocks

Much of the knowledge about the status of Fraser Chinook salmon is based on spawnerescapement data. Most of these data are from visual surveys, which are generally biased low,
although many estimates are considered to be precise (Parken et al. 2003). Escapement estimates determined from visual survey data are usually obtained by dividing the peak count of spawners, holders and carcasses by 0.65 (Farwell et al. 1999; Bailey et al. 2000). The DFO continues to evaluate the accuracy and regularly updates estimates based on the peak count method through calibration studies on Middle Shuswap, Lower Chilcotin, Chilko, and periodically, Lower Shuswap. Escapement has also been estimated at several locations using MR methods, and direct counts at fences or from electronic files collected using sonar and resistivity counter technology. Occasionally escapement estimates could not be determined for reasons including forest fires and extreme weather events that cause power outages at electronic counters or cancellation of visual surveys. When this occurs, missing estimates are infilled using the English method (English et al. 2007).

Fraser River Chinook are assessed as five naturally spawning stock groups for PSC management including Fraser Spring-Run 1.2, Fraser Spring-Run 1.3, Fraser Summer-Run 1.3, Fraser SummerRun 0.3, and the Harrison River (Fall-Run 0.3; Appendix Table B.6). Historically, they were only represented by two stocks in the CTC Model (Fraser Early and Fraser Late). As part of the CTC Model Improvements program and the 2019 Agreement, the Fraser Early model stock has been separated into four model stocks to better represent population dynamics, ocean fishery distribution and maturation patterns, whereas the Fraser Late (Fraser Fall 0.3) model stock has been separated into two stocks, Harrison (natural) and Chilliwack (hatchery), to represent differences in production dynamics and maturation.

The terminal run estimates in Appendix B6 include catch estimates derived from the Fraser run reconstruction model for CTC stocks only (English et al. 2007).

Within the Fraser River basin, prior to the 2019 Agreement, there were five CWT-indicator stocks; Nicola River (Fraser Spring-Run 1.2), Lower Shuswap (Fraser Summer-Run 0.3), Harrison River and Chilliwack River (Fraser Fall 0.3), and Dome Creek (Fraser Spring-Run 1.3), which was discontinued in 2005. Two new CWT-indicator stocks are under development: Lower Chilcotin (Fraser Spring 1.3) to replace Dome Creek, and Chilko River (Fraser Summer 1.3). The Lower Chilcotin River Chinook salmon population spawns within the Chilcotin system between the confluence with the Chilko River and Chilcotin Lake ( 30 km ). CWTs are also applied and recovered at Middle Shuswap and analyzed as part of the CTC Exploitation Rate Analysis (ERA) to increase recoveries in the Fraser Summer-Run 0.3 stock group as part of the escapement estimation for all Fraser Summer-Run 0.3 Chinook spawning in the Thompson River, with most in the South Thompson tributary (PSC 2018).

Lower Shuswap and Harrison Rivers have PSC management goals identified in the 2019 Agreement. For the spring and summer stock groups, habitat-based models have been developed to estimate spawning capacity and the spawner abundance required to produce maximum sustainable yield, $\mathrm{S}_{\mathrm{msy}}$ (Parken et al. 2006). In 2014, a CSAP meeting examined the status and benchmarks for Southern BC Chinook conservation units (CUs), including Fraser. Benchmarks and status were accepted for non-enhanced CUs, but further work on enhanced CUs is required to evaluate status.

In 2019, the Big Bar Landslide on the Fraser River mainstem restricted migration of some populations in the Fraser Spring-Run 1.3 and Fraser Summer-Run 1.3 stock groups, including
both the developing indicator stocks in Lower Chilcotin River and Chilko River. The slide continued to impact migration in 2020 despite significant efforts to improve passage. Mortality rates will be estimated from the telemetry data collected in 2020. Preliminary results indicate the mortality rate was lower in 2020 than in 2019 for both Spring 1.3 and Summer 1.3 stocks.

There have been four consecutive years of low escapements to the three Fraser stock groups with yearling smolt life history (Spring 1.2, Spring 1.3; and Summer 1.3) and the Harrison (Fall 0.3 ). The Nicola River escapement estimate has only met the agency approved management goal once in the past 16 years and was low again in 2020. The Harrison River has only met the CTC-agreed escapement goal once in the past nine years and was well below the escapement goal in 2020 (Figure 2.33). These four stock groups are of conservation concern. The Fraser Summer-Run 0.3 increased during the 1990s and remained abundant until 2012; were lower from 2016-2018; and higher again in 2019 and 2020. Lower Shuswap exceeded the CTC-agreed escapement goal in 2020.

### 2.3.3.4.1 Fraser River Spring Run: Age 1.3

The Fraser River Spring-Run age-1.3 stock group includes spring-run populations of the Lower, Middle and Upper Fraser, North Thompson, and South Thompson, but excludes the Lower Thompson tributaries (CTC 2002). The 2020 Fraser Spring 1.3 escapement estimate $(17,136)$ was the highest since 2015 and is 71\% of the 1975-2020 average escapement (Figure 2.25).

Escapement Methodology: Escapements are typically estimated by expanded peak counts of spawners, holders, and carcasses, surveyed from helicopters or on foot. The Lower Chilcotin River is a new escapement indicator, with escapement estimated by conducting electronic counts, recovering carcasses, and it is being developed as a CWT exploitation rate indicator stock (Figure 2.26). The Lower Chilcotin River estimated escapement of 3,294 in 2020 was $127 \%$ of the time series average ( 2,588 ; Figure 2.26).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock group. Habitat-based estimates of $\mathrm{S}_{\text {msy }}$ and other stock-recruitment reference points are available, but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by electronic counter methods. The Lower Chilcotin is the indicator for the Spring-Run 1.3 stock group identified in Attachment I of the 2019 Agreement. Since 2015, the Lower Chilcotin River escapements have been less than the median habitatbased estimate of $\mathrm{S}_{\text {MSY }}(4,400)$.

Agency Comments: The Fraser Spring 1.3 stock group is of high conservation concern as escapement estimates have declined substantially over the last decade. There have been four consecutive years of very low returns and 2019 had the lowest escapement estimate in 44 years, largely due to the substantial mortality from the Big Bar Landslide obstruction. The escapement in 2020 represents an increase over the 2016-2019 period, but still remains below brood year escapement. In this stock group there are six Conservation Units, used for the DFO Wild Salmon Policy, and six Designatable Units (DUs), assessed by the Committee on Status of Endangered Wildlife in Canada (COSEWIC) as part of Canada's Species at Risk Act (SARA). Four of the DUs were identified as Endangered, one as Threatened, one as Special Concern and one has not yet been assessed by COSEWIC.

Figure 2.25-Fraser River spring run age-1.3 stock group escapements of Chinook salmon, 19752020.

Figure 2.26-Lower Chilcotin River escapements of Chinook salmon, 1975-2020.

### 2.3.3.4.2 Fraser River Spring Run: Age 1.2

The Fraser spring run age-1.2 stock group includes six smaller body size populations that spawn in the Lower Thompson River tributaries, Louis Creek of the North Thompson and the springrun fish of Bessette Creek in the South Thompson (CTC 2002). This stock group has an early maturation schedule for a stream-type life history, with an average generation time of 4.1 years (brood years 1985-1986), which results in smaller body size and lower fecundity compared to
other stock groups. The 2020 Fraser 1.2 stock group escapement estimate was 8,463 , which is 81\% of the 1975-2020 average escapement (Figure 2.27).

Escapement Methodology: For the CTC time series, escapements are estimated using expanded visual peak counts of spawners, holders, and carcasses in Spius Creek, Coldwater River, and Louis Creek. Escapements to the Deadman and Bonaparte rivers are estimated by resistivity counter. Mark-recapture and calibrated visual surveys are used to estimate escapement to the Nicola River.

The Nicola River is the indicator for the Fraser Spring 1.2 stock group in Attachment I of the 2019 Agreement and it is also the exploitation rate indicator stock. Since 1995, high precision escapement estimates (by age and sex) have been generated using an MR program where Petersen disk tags are applied by angling and post-spawned carcasses are examined for the presence of marks. Estimates of escapement have been generated using pooled Petersen and stratified Darroch methods. The expanded peak count time series for the Nicola River is generally less than the MR estimates (Parken et al. 2003); therefore, the Nicola peak count series has been calibrated to the MR data and is used prior to 1995 in the Fraser Spring-run Age 1.2 aggregate time series (Figure 2.27 and Figure 2.28).

The Nicola River MR estimated escapement of 3,955 in 2020 was $72 \%$ of the time series average $(5,519)$. Since 1995 , hatchery origin fish have averaged $28 \%$ of Nicola spawning escapement (range: 4\%-74\%); and they represented $38 \%$ of the spawning escapement in 2020.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this aggregate. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for this stock group (Parken et al. 2006), but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR and electronic resistivity counter methods. In 2019, the habitat-based $\mathrm{S}_{\text {MSY }}$ for the Nicola was updated to 6,600 by removing unsuitable habitat upstream of Nicola Lake and adjusting for the lower than average fecundity to account for the females having a small body size as the majority mature at age 1.2. Since 2014, the Nicola River escapements have been less than the median habitat-based estimate of $S_{M S Y}(6,600)$.

Agency Comments: The stock group has declined substantially over the last decade and is a stock of conservation concern. In this stock group there are two Conservation Units, used for the DFO Wild Salmon Policy, and 2 DUs assessed by COSEWIC as part of SARA. Only one of the DUs has been assessed by COSEWIC (Endangered), and the assessment for the other DU is expected over the next year.

Figure 2.27-Fraser River spring run age-1.2 stock group escapements of Chinook salmon, 19752020.

Figure 2.28-Nicola River escapements of Chinook salmon, 1975-2020.

### 2.3.3.4.3 Fraser River Summer Run: Age 1.3

The Fraser River summer run age-1.3 aggregate includes 10 populations spawning in large rivers, mostly below the outlets of large lakes. These include the Chilko, Nechako, and Quesnel rivers in the Mid-Fraser and the Clearwater River in the North Thompson watershed (CTC 2002). The 2020 Fraser Summer 1.3 escapement estimate $(13,166)$ was the highest since 2015, but was still only $67 \%$ of the 1975-2020 average escapement (Figure 2.29).

Escapement Methodology: Escapements are estimated by expanded peak counts of spawners, holders, and carcasses surveyed from helicopters. Surveys of the Stuart River and North Thompson River were discontinued in 2004 due to unreliable counting conditions and removed from the data series. Mark-recapture and calibrated visual surveys are used to estimate escapement to the Chilko River. From 2010-2018 MR methods were used at Chilko River with tags being applied to live fish captured by seining and salmon carcasses being examined later for the presence of marks. Estimates of escapement have been generated using pooled Petersen and stratified Darroch methods.

The Chilko River estimated escapement of 6,195 in 2020 was $74 \%$ of the time series average (8,392; Figure 2.30).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for the aggregate. Habitat-based estimates of $S_{\text {MSY }}$ and other stock-recruitment reference points are available for this stock group, but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR and AUC methods. The Chilko River is the indicator stock for the Summer-Run 1.3 stock group and for the first time since 2016 the escapement estimate was higher than the median habitat-based estimate of $\mathrm{S}_{\text {MSY }}(4,500)$.

Agency Comments: The Fraser Summer 1.3 stock group is of high conservation concern as escapement estimates have declined substantially over the last decade, there have been four consecutive years of very low returns, and 2018 and 2019 are the two lowest escapement estimates in 44 years. While 2020 escapement is an improvement over 2018 and 2019, escapement was still below both the long term average and brood year (2015) escapement. In this stock group there are five Conservation Units, used for the DFO Wild Salmon Policy, and five Designatable Units, assessed by COSEWIC as part of SARA. Two of the DUs were identified as Endangered, two as Threatened and one has not yet been assessed by COSEWIC.

Figure 2.29-Fraser River summer run age-1.3 stock group escapements of Chinook salmon, 1975-2020.

Figure 2.30-Chilko River escapements of Chinook salmon, 1975-2020.

### 2.3.3.4.4 Fraser River Summer Run: Age $\mathbf{0 . 3}$

The Fraser summer run age- 0.3 aggregate includes six populations spawning in the South Thompson watershed and one in the lower Fraser. These include the Middle Shuswap, Lower Shuswap, Lower Adams, Little River, and the South Thompson River mainstem, in the BC interior, and Maria Slough in the lower Fraser (CTC 2002). The 2020 escapement estimate of 147,504 is high for this stock group and is above both the 2016 parental brood escapement and the 1975-2020 average (Figure 2.31).

Escapement Methodology: Escapements are estimated using peak count visual survey and MR methods. The Lower Shuswap River is the indicator stock identified in Attachment I of the 2019 Agreement and it is the exploitation rate indicator stock. Since 2000 (with the exception of 2003), a MR program provides high precision estimates of escapement by age and sex at the Lower Shuswap River. Tags have been applied to live fish by seining and salmon carcasses were examined later for the presence of marks. Estimates of escapement have been generated using pooled Petersen and stratified Darroch methods. In addition, there are multiple years of MR and CWT data for the Middle Shuswap River.

Since 2000, hatchery-origin fish averaged 12\% of the Lower Shuswap escapement (range: 4\%$22 \%$ ); and they were $16 \%$ of the escapement in 2020.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for the aggregate. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for this stock group (Parken et al. 2006), but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR methods and novel methods developed during the Sentinel Stocks Program. Peak count estimates for the Lower Shuswap River from 1975 to 1999, and for 2003 have been calibrated to MR equivalents.

In the past two decades, with the exception of 2012 and 2016, Lower Shuswap River escapement estimates have exceeded the PSC management objective of 12,300 escapement, which is the median habitat-based estimate of $\mathrm{S}_{\mathrm{MSY}}$ (Figure 2.32).

Agency Comments: Escapements had been increasing for this stock group over the last decade and the stock group has been healthy and abundant, with the exception of the 2012 and 2016 escapement (largely the progeny of the 2012 brood year escapement). In this stock group there are three Conservation Units, used for the DFO Wild Salmon Policy, and two Designatable Units, assessed by COSEWIC as part of Canada's SARA. One DU was identified as not being at risk of extinction and one has not yet been assessed by COSEWIC.

Figure 2.31-Fraser River summer run age-0.3 stock group escapements of Chinook salmon, 1975-2020.

Figure 2.32-Lower Shuswap River escapements of Chinook salmon, 1975-2020.
Note: The visual escapement estimates have been calibrated with the mark-recapture estimates.

### 2.3.3.4.5 Fraser River Late Run (Harrison River)

The Fraser River fall run age- 0.3 is Harrison River Chinook salmon, which are white-fleshed fish that return to spawn during the fall. These Chinook salmon are unusual in that the fry migrate into the lower Fraser River and estuary shortly after emergence. This stock spends 2-4 years in the coastal marine environment before returning to spawn. When healthy, the Harrison River stock is one of the largest naturally spawning Chinook salmon populations in the world and makes important contributions to fisheries in southern British Columbia (B.C.), and Washington State. Spawning escapements to the Harrison River have varied widely from a low of 28,616 adults in 1995 to a high of 246,986 adults in 2003 (Figure 2.33). Escapements have been more than $15 \%$ below the lower bound of the escapement goal since 2012 (excluding 2015), the estimated escapement in 2020 was 43,087 adult Chinook salmon.

Escapement Methodology: Since 1984, MR studies have been conducted annually on the Harrison River to obtain reliable estimates of spawning escapements by age and sex. Tags have been applied to live fish by seining and salmon carcasses are examined later for the presence of marks. Since 1984, hatchery-origin fish averaged $4 \%$ of the escapement (range: $0.3 \%-16.8 \%$ ) and were estimated to be $5 \%$ of the escapement in 2020.

Escapement Goal Basis: Due to their natural abundance and importance in numerous British Columbia and Washington State fisheries, Harrison River Chinook salmon were designated as an escapement indicator stock (i.e., 'key stream' indicator) to aid in fulfilling commitments under the 1985 Pacific Salmon Treaty. In 1986, an interim escapement goal for Harrison River Chinook salmon was established at 241,700 fish, based on doubling of the escapement estimate obtained from a MR program in 1984. In 2001, an escapement goal range was developed for

Harrison Chinook salmon using a Ricker stock-recruit approach (CTC 2002). The escapement goal range that was proposed was $75,100-98,500(C V=15 \%)$ with the upper bound equal to the upper $75 \%$ confidence limit derived from a bootstrap procedure. This range was reviewed and accepted by the CTC. Attachment I of the 2019 Agreement identifies a management objective of 75,100 . Escapements have fluctuated substantially with no apparent trend in the time series, until the recent period of poor returns.

Agency Comments: The Fraser Fall 0.3 stock group is a conservation concern due to very low escapement estimates relative to the escapement goal for the past eight years, excluding 2015. In this stock group there are one Conservation Unit, used for the DFO Wild Salmon Policy, and one Designatable Unit, assessed by COSEWIC as part of Canada's Species at Risk Act. The Harrison DU was identified as Threatened by COSEWIC.

Figure 2.33-Harrison River escapements of Chinook salmon, 1984-2020.

### 2.3.4 Puget Sound, Coastal Washington, Columbia River, and Coastal Oregon Stocks

The PSC escapement indicator stocks in Washington and Oregon are currently separated into four regional groups: Puget Sound, Washington Coastal, Columbia River, and North Oregon Coastal. Far north migrating Chinook salmon from the mid-Oregon Coast were recently incorporated into the PSC Chinook Model with implementation of the Phase II model configuration. There are currently no CTC-accepted escapement indicator stocks for the MidOregon Coastal group, although the South Umpqua and Coquille have been proposed.

Biologically based escapement goals have been reviewed and accepted by the CTC for four fall stocks (Queets, Quillayute, Hoh, and Grays Harbor) and two spring/summer stocks (Queets and Hoh) in the Washington coastal stock group, four Columbia River stocks (Lewis, Upriver Brights, Deschutes, and Mid-Columbia Summers), and three far north migrating Oregon coastal stocks
(Nehalem, Siletz, and Siuslaw). Deschutes fall Chinook, which are part of the Upriver Bright management group, are no longer included as a separate escapement indicator.

### 2.3.4.1 Puget Sound

Puget Sound escapement indicator stocks include spring, summer/fall and fall Chinook salmon stocks from the Nooksack, Skagit, Stillaguamish, Snohomish, Lake Washington, and Green river systems. They tend to have a more local marine distribution than most coastal and Columbia River stocks and are caught primarily in WCVI AABM fisheries and Canadian and U.S. ISBM fisheries. Escapement for these stocks is defined as the total number of natural- and hatcheryorigin fish observed on the spawning grounds.

### 2.3.4.1.1 Nooksack River

The Nooksack River drains into Puget Sound just north of Bellingham. The Nooksack spring Chinook stock includes early-timed populations returning to the North and South forks.

Escapement Methodology: Prior to 1999, estimates of the spring run type escapement in the South Fork were based on the number of redds observed prior to the first of October, expanded by 2.5 spawners per redd. Since 1999, this South Fork estimate has been refined using CWTs, adipose fin clips, and thermal otolith marks to estimate the number of hatchery- and naturalorigin fish in the spawning population. Beginning in 2008 and applied retroactively back to 1999, micro-satellite DNA has been used to assign fish sampled through the first week of October to geographic and run type origin, i.e., North and Middle Fork, South Fork, or hatcheryorigin, and spring or fall run type. Most of the escapement is composed of hatchery-origin returns from two supplementation programs. Estimates of escapement in the North and Middle Fork are based on a combination of field methods, dictated by the influence of glacial runoff; methods include redd and carcass counts in clear tributaries as well as in mainstem (turbid) reaches during clear/low-flow conditions. While all forks are considered spring Chinook, note that the South Fork spring Chinook have a slightly later run timing than the North and Middle Fork. There are no natural Nooksack Fall Chinook populations and, though there have been hatchery releases in the past, fall releases have been discontinued in recent years. Proportions of hatchery-origin fish are calculated from the number of fish identifiable to hatchery origin out of the total observed during carcass sampling. The 2018 estimate of total spawners is 3,117, with 510 total natural-origin spawners (NOR) (Figure 2.34). Escapement estimates from 2019 and 2020 are not yet available for either stock.

Since the 2008 return year, WDFW has been investigating the use of transgenerational genetic mark-recapture (tGMR) methods to estimate spawning escapement of spring Chinook. One finding of the tGMR study (Seamons and Rawding, 2017) was that escapement estimates using the tGMR techniques ranged from 1.2 to 3.1 times higher than escapement estimates obtained from carcass and redd count data (Figure 2.35). These tGMR results represent estimates from the combined populations (all forks) and do not differentiate between hatchery origin or natural origin. The co-managers will review results of the tGMR studies to determine the applicability to the system.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.

Agency Comments: The state-tribal escapement goal established for this Chinook management unit is an upper management threshold (UMT) of 1,000 combined North Fork and Middle Fork natural-origin spawners and a UMT of 500 South Fork natural-origin spawners. The low abundance threshold (LAT) is 400 combined North and Middle Fork natural-origin spawners and 200 South Fork natural-origin spawners. The UMT established by the state-tribal managers is generally considered as the adult (age $3+$ ) escapement level associated with maximum sustained harvest. The LAT is the escapement level below which dramatic declines in long-term productivity could occur. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has operated under a ceiling ER.

Figure 2.34-Nooksack River escapement of total (natural- and hatchery-origin) spring Chinook salmon, 1984-2018. The transgenerational genetic mark-recapture (tGMR) estimates are represented by the points with legend label: Esc (MR).

Figure 2.35-Nooksack River escapements of Chinook salmon to the spawning grounds in years when both agency expanded redd counts were used (circles) and when transgenerational genetic mark-recapture estimates were conducted with Treaty-related funding (diamonds are point estimates and the bars are 95\% CIs).

### 2.3.4.1.2 Skagit River Spring

The Skagit River drains into northern Puget Sound near Mount Vernon and is the largest drainage basin in Puget Sound. The Skagit River spring Chinook salmon stock includes earlytimed populations returning to the Upper Sauk, Upper Cascade, and Suiattle rivers.

Escapement Methodology: Due to changes in spawning index areas, beginning in 1992 for the Cascade stock and 1994 for the Sauk and Suiattle stocks, escapements are not directly comparable to previous numbers. In the Upper Sauk, cumulative redd counts are conducted from river mile (rm) 31.0 to 39.7 (Cascade below White Chuck River mouth to the confluence of the North and South Fork Sauk), in the North Fork Sauk from the mouth to the falls, and in the South Fork Sauk (rm 0 to 5.0). This method replaced the peak live and dead count approach used in prior years. In the Cascade River, cumulative redds are counted in the mainstem upstream of rm 8.1 to the forks at 18.6 encompassing the lower north fork and south fork, and in Found, Kindy, and Marble creeks. In the Suiattle basin, cumulative redds are counted in mainstem Suiattle, and in Big, Tenas, Straight, Circle, Buck, Lime, Downey, Sulphur, and Milk creeks. Prior to 1994, peak live and dead fish counts in Big, Tenas, Buck, and Sulphur creeks were used. Escapement may include very small numbers of hatchery strays in these natural production areas. Past PSC-funded studies on straying of Marblemount Hatchery spring Chinook salmon focused on the area immediately adjacent to the hatchery, which is outside the survey reach for natural production. The preliminary 2020 escapement estimate is 1,449 natural spawners (Figure 2.36; subject to review and revision by co-managers).

Escapement Goal Basis: Attachment I of the 2019 PST Agreement lists an escapement goal of 690 for the Skagit Spring Chinook stock. The escapement goal is the median estimate of escapement that would produce the $S_{\text {MSY }}$. The estimate of $S_{\text {MSY }}$ was calculated using a Bayesian state-space model with two major components: a process model describing the production of age-specific recruits, and observation models to account for errors in the estimates of spawning escapement and age composition. The stock-recruit relationship used to estimate $\mathrm{S}_{\text {MSY }}$ was a Ricker curve, which was chosen instead of a Hockey Stick or Beverton-Holt model as these models tended to overestimate recruitment at low abundances for the Skagit Spring population.

Agency Comments: State-tribal co-managers and National Oceanic and Atmosphere Administration (NOAA) Fisheries are in the process of establishing new domestic management objectives and escapement goals for the Skagit Spring stock. In 2020, the co-managers implemented a UMT of 2,000 natural-origin spawners and an LAT of 823 natural-origin spawners. These objectives are currently being reviewed and may be updated in the future following additional technical analysis. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been operated under a total exploitation rate ceiling rather than for a UMT or LAT escapement.

Figure 2.36-Skagit River escapement of spring Chinook salmon to the spawning grounds, 19752020.

Note: This includes early-timed populations returning to the Upper Sauk, Upper Cascade, and Suiattle rivers.

### 2.3.4.1.3 Skagit River Summer/Fall

The Skagit River summer/fall Chinook salmon stock includes the Upper Skagit River summer, Sauk summer, and Lower Skagit River fall run populations.

Escapement Methodology: Escapement of Skagit River summer/fall Chinook salmon was estimated using expansion of redd counts from helicopter surveys of mainstem areas and foot surveys of smaller tributaries. The counts are expanded by the AUC method (Smith and Castle 1994). This method assumes a 21 -day redd life and 2.5 adult spawners per redd. Natural escapement is predominantly offspring from natural-origin spawners; the remainder are hatchery-origin fish from the wild stock tagging program that started in 1994. Natural escapement does not include the brood stock collected for this program. The preliminary 2020 escapement estimate is 10,835 natural spawners (Figure 2.37; subject to review and revision by co-managers).

Escapement Goal Basis: Attachment I of the Pacific Salmon Treaty lists an escapement goal of 9,202 for Skagit River Summer/Fall Chinook. The escapement goal is the median estimate of escapement that would produce the $S_{M S Y}$. The estimate of $S_{M S Y}$ was calculated using a Bayesian state-space model with two major components: a process model describing the production of age-specific recruits, and observation models to account for errors in the estimates of spawning escapement and age composition. The stock-recruit relationship utilized to estimate $\mathrm{S}_{\text {MSY }}$ was a Ricker curve, which was chosen instead of a Hockey Stick or Beverton-Holt model as these models tended to overestimate recruitment at low abundances for the Skagit Fall population.
Agency Comments: The UMT used by the state-tribal comanagers for the Skagit River summer/fall Chinook salmon management unit is 14,500 , based on a recent assessment of freshwater productivity and accounting for variability and biases in management error (CCMP 2010). The LAT is 9,100 spawners. Since its listing as threatened under the ESA in 1999, annual fishery management for this stock has been operated under a total exploitation rate ceiling rather than for a UMT or LAT escapement. In years when the UMT is expected to be exceeded, terminal fisheries can be expanded subject to the overall total ceiling exploitation rate.

Figure 2.37-Skagit River escapement of summer/fall Chinook salmon to the spawning grounds, 1975-2020.

### 2.3.4.1.4 Stillaguamish River

The Stillaguamish River drains into northern Puget Sound between Everett and Mount Vernon. The Stillaguamish River has two populations of Chinook salmon distinguished by genetic characteristics-a summer-timed run and a fall-timed run. These two populations overlap in spawn timing and distribution with both populations spawning in both forks of the river. The summer-timed run is a composite of natural- and hatchery-origin supplemental production, with most spawning occurring in the North Fork and its major tributaries, including Boulder River, and Deer, Grant, French, and Squire creeks with some spawning occurring in the South Fork Stillaguamish. The fall-timed run is a natural-origin fall stock with recent increases in supplementation with hatchery-origin production that spawns primarily in the mainstem and South Fork Stillaguamish, in Pilchuck, Jim, and Canyon creeks, and a small portion spawning in the North Fork Stillaguamish River. Escapement is currently estimated as total watershed abundance, including both summer and fall populations of Chinook salmon.

Escapement Methodology: Historically, geographic based (North Fork/South Fork) escapement estimates for Stillaguamish Chinook salmon were based on a peak redd count expansion, assuming 2.5 fish per redd.

Spawning escapement estimates are biased low due to incomplete redd counts using visual sampling methods (Figure 2.38). Evidence of this is supported by results of tGMR studies that have occurred in recent years, funded by Treaty-related sources (Small et al. 2020). Escapement estimates based on these studies were on average 1.26 (0.96-2.14) times higher than those calculated from redd count data (Figure 2.39).

Therefore, the co-managers agreed to revise escapement estimates from 1988 to 2007 to a tGMR equivalent estimate. First, aerial survey-based escapement estimates for total watershed are adjusted to a ground survey-based equivalent using data collected in 2008, 2009, 2016, and 2017 when aerial and ground surveys were conducted concurrently. The adjusted ground count escapements are converted to a tGMR equivalent using a regression relationship derived from ground based and tGMR escapements from the period 2008 to 2016 when both methods were used concurrently. Since 2008, funding has been available to continue the tGMR study, with results of the genetics lab hypergeometric estimate adopted as final agreed to escapement estimates.

Lab results are not available for 2020 pre-season planning at this publication, a provisional escapement converting the ground count escapement to a tGMR equivalent is derived, estimating a naturally spawning escapement estimate of 850 total spawners. An additional 137 fish were collected for broodstock from the spawning grounds. Of the total 987 spawners, $61 \%$ were estimated to be of hatchery origin.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock group.
Agency Comments: State-tribal co-managers and NOAA Fisheries are in the process of finalizing a plan for new domestic management actions and escapement objective for the Stillaguamish stock. In 2018, the co-managers implemented a UMT of 1,500 total (hatcheryplus natural-origin) spawners. The summer Chinook salmon supplementation program, which collects brood stock from the North Fork of the Stillaguamish River return, was initiated in 1986 as a PST indicator stock program, and its current objective is to release 220,000 coded wire
tagged and adipose clipped fingerling smolts per year from Whitehorse Ponds Hatchery facility in the upper North Fork Stillaguamish. Since 2000, an average of 140 adults have been collected annually from the spawning population for this program. In 2009, a captive brood fall timed hatchery program which collects broodstock from juvenile outmigrants, was implemented at Brenner Creek Hatchery facility in the upper South Fork Stillaguamish, and the first release was in 2013. The current objective is 200,000 coded-wire tagged and adipose clipped fingerling smolts per year, with recent releases slightly above 100,000 and increasing. Since listing as threatened under the ESA in 1999, annual fishery management for this stock has been operated under a ceiling exploitation rate determined by the forecast abundance tier.

Figure 2.38-Stillaguamish River escapement of Chinook salmon to the spawning grounds, 19752020.

The points labeled Esc (MR) represent new estimates based on recent surveys applying transgenerational genetic mark-recapture (tGMR) estimates.

Figure 2.39-Stillaguamish River escapements of Chinook salmon to the spawning grounds in years when both agency expanded redd counts were used (circles) and when transgenerational genetic mark-recapture estimates were conducted with Treaty-related funding (diamonds).

### 2.3.4.1.5 Snohomish River

The Snohomish River is in northern Puget Sound near Everett. The Snohomish Chinook salmon stock includes the Skykomish and Snoqualmie summer/fall run populations. Skykomish Chinook salmon spawn in the mainstem of the Skykomish River and its tributaries-including the Wallace and Sultan rivers, Bridal Veil Creek, the south fork of the Skykomish River between river mile 49.6 and river mile 51.1, above Sunset Falls (fish have been transported around the falls since 1958), and the North Fork of the Skykomish River up to Bear Creek Falls (rm 13.1). Snoqualmie Chinook salmon spawn in the Snoqualmie River and its tributaries, including the Tolt River, Raging River, and Tokul Creek.

Escapement Methodology: Escapement was estimated using expanded redd counts obtained by a combination of helicopter, float, and foot surveys, and from fish counts at the Sunset Falls fishway. The natural spawning escapement estimate includes a significant contribution of hatchery strays from the Wallace and Bernie Kai-Kai Gobin (Tulalip Tribes) facilities. Annual tGMR studies funded under the SSP were conducted from 2011-2015 (Figure 2.40 and Figure 2.41). The 2020 escapement is estimated at 3,932 natural spawners.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.
Agency Comments: The state-tribal co-managers have a UMT for this stock of 4,900 naturalorigin spawners. The LAT for Snohomish River summer/fall Chinook salmon is 3,250. Since listed as threatened under the ESA in 1999, annual fishery management for this stock has been for a ceiling exploitation rate determined by abundance tier. In 2014, WDFW and the Tulalip Tribes reviewed, reconciled, and updated the historic escapement time series for the Snohomish Basin; this resulted in minor changes to the data series.

Figure 2.40-Snohomish River escapement of Chinook salmon to the spawning grounds, 19752020.

The transgenerational genetic mark-recapture estimates are represented by the points with legend label: Esc (MR).

Figure 2.41-Snohomish River escapements of Chinook salmon to the spawning grounds in years when both agency expanded redd counts were used (circles) and when transgenerational genetic mark-recapture estimates were conducted with Treaty-related funding (diamonds are point estimates and the bars are $95 \% \mathrm{Cls}$ ).

### 2.3.4.1.6 Lake Washington

The Lake Washington Chinook salmon stock includes the fall run populations in the Cedar River and in the Sammamish River tributaries of Bear, Cottage, and Issaquah creeks. A hatchery is located on Issaquah Creek, and Chinook salmon at the hatchery rack are not included in the natural escapement for Lake Washington.

Escapement Methodology: Escapement in the mainstem Cedar River is estimated using expansion of total redd counts. Prior to 1999, live counts and AUC methods were used to estimate spawning abundance in the Cedar River. Past AUC estimates have been converted to redd-based estimates using simple linear regression. Escapement estimates are considered a complete census because redd surveys encompass the entire Chinook production area of the Cedar River. It should be noted that although there are no hatchery fish released into the Cedar River, an average of $24 \%$ of the spawners from 2003 to 2020 were hatchery origin, originating primarily from Issaquah Hatchery.). Escapement to the Sammamish River tributaries is estimated using live counts and AUC methods in Bear and Cottage Lake creeks. Index surveys in Bear Creek began in 1981; index surveys in lower Cottage Lake Creek began in 1983 and were expanded in 1997 to include upper Cottage Lake Creek (considered a non-index area). Spawning escapement based on AUC methods in Issaquah Creek below the Issaquah Creek Hatchery rack and East Fork Issaquah Creek were initiated in 1999. Past AUC estimates of index areas have been converted to AUC estimates of both index and non-index areas using simple linear regression. The majority (90\%) of natural spawners in the Sammamish River tributaries are hatchery-origin, likely strays from the Issaquah hatchery. The 2020 naturally spawning escapement estimate for Lake Washington is 2,219 of which 513 were attributed to the Cedar River and 1,706 (of which 59 were natural-origin fish) to the Sammamish River tributaries (Figure 2.42).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.
Agency Comments: State-tribal co-managers and NOAA Fisheries are in the process of establishing new domestic management objectives and escapement goals for the Lake Washington stock. In 2018, the co-managers developed an MSY based escapement goal (282) for the Cedar River population and but are managing for 500 natural spawners with an LAT of 200 natural spawners. Since listed in 1999 as threatened under the ESA and through 2017, annual fishery management for the Cedar River stock has operated under a ceiling exploitation rate rather than for a spawning escapement goal.

Figure 2.42-Escapement of Chinook salmon to the spawning grounds in the tributaries of Lake Washington (Cedar River and Bear and Cottage Lake Creeks), 1975-2020.

### 2.3.4.1.7 Green River

The Green River fall Chinook salmon stock consists of a single population spawning in the mainstem Green River and two of its major tributaries, Newaukum and Soos creeks.

Escapement Methodology: Escapement is estimated from a redd count expansion method that has varied over the time series by the extent of spawning survey coverage. The method used until about 1996 involved an index area redd count multiplied by 2.6 to estimate total redds, then multiplied by 2.5 fish per redd to produce estimated escapement. The 2.6 index to total redd expansion factor was based on a 1976 to 1977 US Fish and Wildlife Service MR study (Ames and Phinney 1977). Since 1996, the survey areas have been broadened and the associated expansion factor of 2.6 has been reduced to the point where redd count surveys in 2009 have complete spawning reach coverage. The method used in recent years provides natural escapement estimates for the mainstem Green River and Newaukum Creek. Newaukum Creek redds are counted during foot surveys. The mainstem Green River is surveyed by boat and by air. Some parts of the river (i.e., the gorge) are only surveyed by air. Boat surveys are generally conducted once a week. One aerial survey is made during the peak of spawning, with more surveys if budgets permit. Certain index reaches of the river are surveyed every week by boat to develop a cumulative redd count total for those reaches. These index reaches are distributed throughout the river. Visible redds are counted for the entire floatable part of the river by boat each week and for the entire river by helicopter during the peak. The ratio of visible redds seen by boat to those seen by air (boat surveys assumed to be best) is used to estimate how many redds would be seen by boat in the reaches not surveyed. This provides an estimate of how many visible redds exist during the peak of spawning. To get from peak redds to cumulative total redds, the visible redds in the index reaches during the peak are compared
to the season total for those index reaches. Different areas of the river have different ratios of peak visible redds to season totals. Expansion of visible redds outside index areas to season total redds uses the ratio from nearby index reaches of the same general character. The CTC considers these estimates from redd counts as index values rather than estimates of total escapement. Estimates of total escapement from MR studies in 2000, 2001, and 2002 funded through the U.S. Letter of Agreement were about 2.5 times higher than the escapement estimate from redd count expansion. In 2010, 2011 and 2012, tGMR-based escapements from studies funded under the SSP were once again more than twice as high as the redd count expansion estimates (Figure 2.43 and Figure 2.44). There is a large hatchery program in this basin and these fish comprise a large portion of the return. Hatchery contribution to the natural escapement in the Green River averaged 58\% from 2004-2019 and ranged from 27\% to 75\%. The 2020 redd-based estimate of naturally spawning escapement is 4,300 mixed hatchery- and natural-origin Chinook salmon.

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.
Agency Comments: State-tribal co-managers and NOAA Fisheries are in the process of establishing new domestic management objectives and escapement goals for the Green River stock. In 2018, the co-managers developed an MSY-based escapement goal of 2,003 and implemented a multi-tiered natural spawning escapement threshold of 3,800 (UMT1) and 6,000 (UMT2) natural spawners and a LAT of 802 natural spawners that regulated exploitation rates for this stock. Since listed as threatened under the ESA in 1999, annual fishery management for this stock has used a ceiling exploitation rate in the southern U.S. preterminal fisheries, and a UMT in the terminal fisheries.

Figure 2.43-Green River escapement of Chinook salmon to the spawning grounds, 1975-2020.
The transgenerational genetic mark-recapture (tGMR) estimates are represented by the points with legend label: Esc (MR).

Figure 2.44-Green River escapements of Chinook salmon to the spawning grounds in years when both agency expanded redd counts were used (circles) and when conventional (20002002) and genetic (2010-2012) mark-recapture estimates were conducted with Letter of Agreement or SSP funding (diamonds are point estimates and the bars are 95\% CIs).

### 2.3.4.2 Coastal Washington

Coastal Washington stocks include spring, summer, and fall Chinook salmon from the Hoko, Quillayute, Hoh, and Queets Rivers, and from Grays Harbor including the Chehalis and Humptulips rivers. Coastal Washington stocks have a northerly distribution and are primarily caught in SEAK and NBC AABM fisheries. They are also caught in southern U.S. terminal net fisheries, primarily as mature fish during their spawning migrations.

### 2.3.4.2.1 Hoko River

The Hoko River is located at the extreme western end of the Strait of Juan de Fuca and is not listed as part of the Puget Sound Chinook Salmon Endangered Species Unit under the ESA. Hoko River Chinook salmon spawn primarily in the mainstem of the Hoko River, with limited spawning in larger tributaries.

Escapement Methodology: The Makah Tribe and WDFW conduct ground surveys using cumulative redd counts for the Hoko River mainstem and tributaries found between rm 1.5 and 21.7, which represents the entire range of spawning habitat utilized by Chinook salmon. Redd counts are multiplied by 2.5 adults per redd. There are 10 mainstem reaches plus 13 tributary reaches, including Little Hoko, Browne's, Herman, North Fork Herman, Ellis, Bear, and Cub rivers, which are all upper mainstem tributaries. The tribe also surveys the mainstem Sekiu River, and Carpenter, South Fork Carpenter, Sunnybrook, and three unnamed creeks (numbered 19.0215, 19.0216, and 19.0218). Escapement excludes fish used as broodstock to
support the supplementation program, which started in 1988 and targets 200 fish each year. In 2020, there was a total natural spawning escapement estimate of 1,060 mixed natural-and hatchery-origin returns from the supplementation program (Figure 2.45).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.
Agency Comments: The UMT escapement goal established by state and tribal co-managers is 850 naturally spawning adults. Instead of a stock-recruitment analysis, the escapement goal was derived using a habitat-based approach where estimates of available spawning habitat were expanded by assumed optimal redds per mile and fish per redd values (Ames and Phinney 1977).

Figure 2.45-Hoko River escapement of Chinook salmon to the spawning grounds, 1986-2020.

### 2.3.4.2.2 Quillayute River Summer

The Quillayute River drains from the northwest side of the Olympic Mountains into the Pacific Ocean, south of Cape Alava on the north Washington coast.

Escapement Methodology: Escapement estimates are based on redd counts in index areas and from supplemental surveys on the Bogachiel, mainstem Calawah, North Fork Calawah, and Sitkum rivers. This has been used consistently in the Quillayute River system since the 1970s. Surveys are conducted by foot, raft, drift boat, and helicopter. Index areas are surveyed either weekly or biweekly as conditions allow. Supplemental surveys are done once a season during the peak spawning period. Redd counts from these supplemental surveys are then expanded by the index surveys to estimate redds within the supplemental survey areas for the entire season. Using an appropriate redds-per-mile assignment, the information from index and supplemental surveys is then applied to other unsurveyed streams and segments with historical fish presence. These areas comprise the Quillayute River system stream mileage base that is consistently
calculated by multiplying the number of redds by 2.5 to estimate escapement. The 2020 escapement estimate was 635 summer Chinook (Figure 2.46).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock.
Agency Comments: The state-tribal management goal for this stock is 1,200 adults and jacks combined (PFMC 2016).

Figure 2.46-Quillayute River escapement of summer Chinook salmon to the spawning grounds, 1976-2020.

### 2.3.4.2.3 Quillayute River Fall

The Quillayute River is one of four Washington coast river systems that contain fall Chinook salmon with PSC-agreed escapement goals.

Escapement Methodology: Escapement estimates are based on redd counts in index areas and from supplemental surveys on the Bogachiel, Sol Duc, Dickey, and Calawah rivers and several other smaller tributaries in the basin. Methods have been consistent in the Quillayute River system since the 1970s. Surveys are conducted by foot, raft, drift boat, and helicopter. Index areas are surveyed either weekly or biweekly as conditions allow. Supplemental surveys are done once a season during the peak spawning period. Redd counts from these supplemental surveys are then expanded by the index surveys to estimate redds within the supplemental survey areas for the entire season. Using an appropriate redds-per mile, the information from index and supplemental surveys is then applied to other streams and segments that historically had fish presence, but were not surveyed. These areas comprise the Quillayute River system stream mileage base that is consistently calculated by multiplying the number of redds by 2.5 to estimate escapement. The 2020 escapement estimate was 8,202 fall Chinook (Figure 2.45).

Escapement Goal Basis: In 2004, the PSC agreed upon an escapement goal of 3,000 natural spawners for Quillayute fall Chinook salmon based on a spawner-recruit analysis developed by Quinault Department of Natural Resources (QDNR 1982) and Cooney (1984).

Agency Comments: Terminal fisheries are managed for a harvest rate of $40 \%$, with an escapement floor of 3,000 fish. This objective was designed to allow a wide range of escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock.

Figure 2.47-Quillayute River escapement of fall Chinook salmon to the spawning grounds, 1980-2020.

### 2.3.4.2.4 Hoh River Spring/Summer

The Hoh River drains from the western side of the Olympic Mountains on the north Washington coast between the Quillayute River to the north and the Queets River to the south.

Escapement Methodology: Escapement is estimated from redd counts in index areas, supplemental surveys in the mainstem and south fork of the Hoh River, and in tributaries with spawning habitat. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record new and visible redds. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Surveys are also conducted in reaches too large or remote to intensively monitor throughout the season. These surveys are timed as close as possible to peak spawning activity, and spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement for these reaches of known stream length. The total natural spawning escapement is calculated assuming
2.5 fish per redd. There is no hatchery program in this system. The 2020 natural escapement estimate was 1,248 fish (Figure 2.48).

Escapement Goal Basis: In 2004, the CTC accepted an escapement floor goal of 900 for the Hoh spring/summer Chinook salmon, that was developed by QDNR (1982) and Cooney (1984) based on spawner-recruit analyses for brood years 1969 to 1976.

Agency Comments: Like many of the other Washington coastal stocks, Hoh River spring/summer escapements have been relatively stable except for much larger returns in 1988, 1989, and 1990. The terminal return for this stock declined from 1997 to 2000 and rebounded in 2001 before declining again from 2006 to 2014. Terminal fisheries are managed to catch $31 \%$ of the river run, with an escapement floor of 900 fish. This objective was designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock.

Figure 2.48-Hoh River escapement of spring/summer Chinook salmon to the spawning grounds, 1976-2020.

### 2.3.4.2.5 Hoh River Fall

The Hoh River is one of four Washington coast river systems that contain fall Chinook salmon with PSC-agreed escapement goals.

Escapement Methodology: Escapement is estimated from redd counts in index areas, supplemental surveys in the mainstem and south fork Hoh River, and in tributaries with spawning habitat. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record total new and visible redds observed each week. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate
timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive but infrequent surveys are also conducted in additional monitored Chinook spawning areas. These reaches encompass areas too large or remote to intensively monitor throughout the season. Surveys are timed as close as possible to peak spawning activity. Spawner abundance estimates from the extensive surveys are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement for these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish per redd. The natural escapement estimates for Hoh River fall Chinook include a small number of fish taken for an experimental hatchery program from 1983 to 1986, but otherwise should be considered natural-origin fish. The 2020 escapement estimate is 2,273 fish (Figure 2.49).

Escapement Goal Basis: In 2004, the CTC accepted an escapement floor goal of 1,200 for Hoh fall Chinook salmon, developed by QDNR (1982) and Cooney (1984) based on spawner-recruit analyses of data from 1968 to 1982.

Agency Comments: The state-tribal management plan for this stock includes a harvest rate of $40 \%$ on the terminal run, with an escapement floor of 1,200 spawners. This objective was designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock.

Figure 2.49-Hoh River escapement of fall Chinook salmon to the spawning grounds, 1976-2020.

### 2.3.4.2.6 Queets River Spring/Summer

The Queets River drains from the western side of the Olympic Mountains on the north Washington coast and is south of the Hoh River.

Escapement Methodology: Escapement is estimated from redd counts from August 15 to October 15 for spring/summer Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record total new and visible redds observed each week. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive but infrequent surveys are also conducted in additional spawning areas. These reaches encompass areas too large or remote to intensively monitor throughout the season and the surveys are timed as close as possible to peak spawning activity. Spawner abundance estimates from the extensive surveys are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish per redd. The 2020 estimate of natural escapement was 342 fish (Figure 2.50).

Escapement Goal Basis: In 2004, the CTC accepted an escapement floor goal of 700 for Queets spring/summer Chinook salmon, developed by QDNR (1982) and Cooney (1984) based on spawner-recruit analyses for brood years 1969 to 1976.

Agency Comments: Terminal fisheries are managed by the state and tribes to catch $30 \%$ of the terminal run, with an escapement floor of 700 fish. This objective was designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock. Since 1990, terminal fisheries on this stock have been limited, as returns to the river have rarely exceeded the escapement floor. Since 2000, sport anglers have been required to release all Chinook salmon during the summer, and tribal fisheries have been limited to one tribal netting day for ceremonial and subsistence purposes.

Figure 2.50-Queets River escapement of spring/summer Chinook salmon to the spawning grounds, 1976-2020.

### 2.3.4.2.7 Queets River Fall

The Queets River drains from the western side of the Olympic Mountains on the north Washington coast and is south of the Hoh River. It is one of four Washington coast river systems that contain fall Chinook salmon with PSC-agreed escapement goals.

Escapement Methodology: Escapement is estimated from redd counts from October 15 to December 1 for fall Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record total new and visible redds observed. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive but infrequent surveys are also conducted in additional monitored spawning areas that are too large or remote to intensively monitor throughout the season. These surveys are timed as close as possible to peak spawning activity. Spawner abundance estimates from these larger areas are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish per redd. The 2020 estimate of Queets River fall Chinook salmon natural escapement was 3,459 fish (Figure 2.51).

Escapement Goal Basis: In 2004, the CTC accepted an escapement floor goal of 2,500 for the Queets fall Chinook salmon, developed by QDNR (1982) and Cooney (1984) based on spawnerrecruit analyses of data from 1967 to 1982.

Agency Comments: Terminal fisheries are managed by the state and tribes to catch $40 \%$ of the terminal run, with an escapement floor of 2,500 spawners. This objective was designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock.

Figure 2.51-Queets River escapement of fall Chinook salmon to the spawning grounds, 19762020.

### 2.3.4.2.8 Grays Harbor Spring

Grays Harbor spring Chinook salmon spawn primarily in the upper reaches of the mainstem Chehalis River and its tributaries.

Escapement Methodology: Escapement is estimated from redd counts from August 15 to October 15 for spring/summer Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record total new and visible redds observed. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Infrequent surveys are also conducted in additional spawning areas that are outside of the index reaches and are too large or remote to intensively monitor throughout the season. These surveys are timed as close as possible to peak spawning activity. Spawner abundance estimates from these larger areas are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish per redd. The 2020 escapement was 2,828 Chinook salmon (Figure 2.52).

Escapement Goal Basis: There is currently no PSC-agreed escapement goal for this stock group.

Agency Comments: The natural spawning escapement goal established by the state-tribal comanagers for Grays Harbor spring Chinook salmon is 1,400 adult fish (PFMC 2016). This goal was developed as an MSY proxy, derived from actual spawning data from the mid- to late 1970s, and expanded to include additional habitat not covered by spawner surveys.

Figure 2.52-Grays Harbor escapement of spring Chinook salmon to the spawning grounds, 1976-2020.

### 2.3.4.2.9 Grays Harbor Fall

Grays Harbor fall Chinook salmon spawn primarily in the mainstem Chehalis River, in the Humptulips and Satsop rivers where fall Chinook salmon hatchery facilities are located, and in smaller tributaries such as the Wishkah and Hoquiam rivers that flow directly into the harbor. The Grays Harbor fall Chinook stock is one of four Coastal Washington fall Chinook stocks that have PSC-agreed escapement goals.

Escapement Methodology: Escapement is estimated from redd counts from October 15 to December 1 for fall Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed weekly to record total new and visible redds observed. Cumulative redd counts for each index reach represent the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive but infrequent surveys are also conducted in additional spawning areas that are too large or remote to intensively monitor throughout the season. These surveys are timed as close as possible to peak spawning activity. Spawner abundance estimates from these larger areas are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds per river mile) from surveyed reaches with similar habitat type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish per redd. The 2020 escapement was 19,800 spawners (Figure 2.53).

Escapement Goal Basis: In 2014, the CTC accepted an escapement goal for Grays Harbor fall Chinook salmon of 13,326 natural spawners based on a spawner-recruit analysis developed by QDNR and WDFW (2014).

Agency Comments: The Grays Harbor fall Chinook salmon escapement goal will be applied in CTC stock-performance evaluations on a stock aggregate basis. This goal, however, is the sum of tributary-specific goals that were derived separately for the Chehalis and Humptulips rivers.

Figure 2.53-Grays Harbor escapement of fall Chinook salmon to the spawning grounds, 19752020.

Note: The displayed agency goal line $(14,600)$ relates to the agency goal in effect through 2013; the recently PSC-agreed escapement goal $(13,326)$ will be used in assessments from 2014 onward.

### 2.3.4.3 Columbia River

Columbia River fisheries are managed under the 2018-2027 U.S. v. Oregon Management Agreement, using six harvest indicators, and eleven abundance indicators.

Harvest indicators are used to directly manage fisheries during three fishing periods, based on the number of adults returning to the river mouth:

| Run (Fishing Period) | Harvest Indicator |
| :---: | :---: |
| Spring <br> 1 January - 15 June | Upriver spring and Snake River spring/summer Chinook |
|  | Natural-origin Snake River spring/summer Chinook |
|  | Natural-origin Upper Columbia spring Chinook |
| $\begin{gathered} \text { Summer } \\ 16 \text { June }-31 \text { July } \end{gathered}$ | Upper Columbia Summer Chinook |
| Fall | Upriver Bright fall Chinook |
| 1 August - 31 December | Snake River natural-origin fall Chinook |

Columbia Upriver Spring Chinook are comprised of all spring Chinook above Bonneville Dam and summer Chinook from the Snake River and are predominantly hatchery fish from the Snake River. These fish have stream-type life histories, migrate quickly offshore, and have fishery impacts that are predominantly terminal. Since they are not listed in Attachment I, they are not addressed in this report.

Upper Columbia Summer Chinook have a northern coastal distribution, demonstrate both ocean- and stream-type life histories, are defined as all summer Chinook above Bonneville Dam during the summer period, and are represented by the Mid-Columbia Summer Chinook PSC indicator stock.

Columbia River Fall Chinook have ocean-type life histories and coastal distributions, but there are two distinctive races. Lower Columbia River "tule" Chinook return below Bonneville Dam, mature quickly, are caught mainly in the WCVI AABM and U.S. ISBM fisheries, and are represented by the Coweeman Tule Fall Chinook PSC escapement indicator. In addition, the PSC monitors Lewis River Wild fall Chinook production below Bonneville Dam. Upriver Bright Fall Chinook, which have more prolonged maturation, are comprised of production above McNary Dam, and in the Deschutes and Snake rivers. Upriver Bright Fall Chinook above McNary Dam have a northerly distribution, and comprise substantial proportions of catch in SEAK, WCVI, and U.S. ISBM fisheries, while Snake and Deschutes river production is predominantly impacted in WCVI and U.S. ISBM fisheries.

Abundance indicator stocks are defined by the U.S. v. Oregon Management Agreement to further monitor status of natural-origin populations that may limit Columbia River fisheries:

| Abundance Indicator Stocks |  |
| :--- | :--- |
| Upriver spring/summer Chinook |  |$|$| Snake R natural-origin spring/ summer <br> Chinook |  |  |  |
| :--- | :--- | :---: | :---: |
| Snake R natural-origin spring/summer Chinook | Upper Columbia R natural-origin spring <br> Chinook |  |  |
| Upper Columbia R natural-origin spring Chinook | Upriver Columbia R natural-origin spring <br> Chinook (Wenatchee, Entiat, Methow) |  |  |
| Upriver Columbia R natural-origin spring Chinook <br> (Wenatchee, Entiat, Methow) | Snake R spring/summer Chinook index <br> stocks (Bear Valley, Marsh, Sulphur, Minam, <br> Catherine Cr., Imnaha, Poverty Flats, <br> Johnson) |  |  |
| Snake R spring/summer Chinook index stocks (Bear <br> Valley, Marsh, Sulphur, Minam, Catherine Cr., Imnaha <br> Poverty Flats, Johnson) | John Day natural-origin spring Chinook |  |  |
| John Day natural-origin spring Chinook Summer Chinook |  |  |  |
| Warm Springs natural-origin spring Chinook | Warm Springs natural-origin spring Chinook |  |  |
|  |  |  | Upper Columbia R summer Chinook |
| Upper Columbia R summer Chinook | Fall Chinook |  |  |
| Hanford natural-origin adult fall Chinook |  |  |  |
| Hanford natural-origin adult fall Chinook | Snake River adult fall Chinook |  |  |
| Snake River adult fall Chinook | Snake River adult fall Chinook |  |  |
| Snake River adult fall Chinook | Deschutes River natural-origin adult fall <br> Chinook |  |  |
| Deschutes River natural-origin adult fall Chinook |  |  |  |

### 2.3.4.3.1 Mid-Columbia Summer

Escapement Methodology: Figure 2.54 displays adult Chinook salmon passing Rock Island Dam between June 18 and August 17; these counts include hatchery fish and recent sport catches above the dam, but are more consistent with the PSC Chinook Model data (hatchery and natural-origin combined) used to develop the interim escapement goal.
Escapement Goal Basis: The CTC (1999) developed an interim escapement goal of 12,143 adult summer Chinook salmon past Rock Island Dam, using PSC Chinook model predictions of escapement and recruitment. A 2008 analysis of actual escapement data resulted in a higher estimate, but the CTC requested addition years of data, so the interim goal remains. The 20182027 U.S. v. Oregon Management Agreement calls for reviewing goals.

Agency Comments: Upper Columbia Summer Chinook are managed for 29,000 adults at the river mouth, based on the co-managers' spawning escapement goal of 20,000 adults at Priest Rapids Dam. Although management is not constrained by individual components, sub-basin objectives are 13,500 Wenatchee/Entiat/Chelan naturally spawning fish, 3,500 Methow/Okanogan natural fish and 3,000 hatchery brood stock. Catches are based on an abundance-based harvest rate schedule (2018-2027 U.S. v. Oregon Management Agreement, Table A2). Harvest rates are near $5 \%$ for run sizes up to 16,000 , and $15 \%$ to $17 \%$ for run sizes up to 36,250 ( $125 \%$ of 29,000 ). Between 36,250 and 50,000 , harvestable surplus is run size less 29,000, and above $50,000,75 \%$ of the additional run becomes harvestable surplus, while the other $25 \%$ is foregone to escapement. Rock Island Dam counts showed a steep decline from 2015-2018, but rebounded in 2020. Escapements are well above goal.

Figure 2.54-Adult passage of Mid-Columbia Summer Chinook salmon at Rock Island Dam, 1979-2020.

### 2.3.4.3.2 Columbia Upriver Brights

Escapement Methodology: Figure 2.55 displays the McNary Dam count minus adult Hanford Reach sport catch, Wanapum tribal catches, and broodstock taken at Priest Rapids, Ringold and Snake River hatcheries.

Escapement Goal Basis: The PSC-agreed escapement goal for Columbia Upriver Brights is 40,000 naturally spawning fish past McNary Dam based on stock-recruitment analyses.

Agency Comments: Upriver Brights are managed according to an abundance-based harvest rate schedule (2018-2027 U.S. v. Oregon Management Agreement, Table A3), and a minimum management goal of 60,000 adult fall Chinook salmon at McNary Dam, which includes Snake River production. The U.S. v. Oregon Parties also agreed to a minimum goal of 43,500 Upriver Bright escapement to provide spawning in the Hanford Reach, Lower Yakima River, and mainstem Columbia River above Priest Rapids Dam, as well as Priest Rapids Hatchery production. Fall Chinook salmon fisheries are managed according to a harvest rate schedule ranging from $21.5 \%$ to $45 \%$, depending on either (1) the expected river mouth run size of the aggregate fall Chinook salmon run, or (2) the Snake River natural-origin Chinook salmon run-if that run size is associated with a lower harvest rate. Constraints on Upriver Bright fisheries include the $15 \%$ harvest rate limit on commingled ESA-listed B-run summer steelhead ( $>78 \mathrm{~cm}$ ) for forecast runs of less than 20,000, ESA-listed Snake River wild fall Chinook salmon impacts, and the need for 7,000 tule fall Chinook salmon for brood stock at Spring Creek Hatchery. Like Mid-Columbia Summer Chinook, Upriver Bright escapement showed a steep decline 2015-2018, and has increased since.

Figure 2.55-Upriver Bright Chinook salmon escapements, 1975-2020.

### 2.3.4.3.3 Coweeman River Tules

The Coweeman River is a $3^{\text {rd }}$ order tributary to the Cowlitz River located in Cowlitz County, Washington and drains approximately $329 \mathrm{~km}^{2}$. This watershed supports a small population of mostly natural-origin 3 and 4 -year-old tule fall Chinook salmon. The Coweeman escapement indicator stock represents ESA-listed natural tule fall Chinook salmon production from the Lower Columbia River.

Escapement Methodology: From 2002 to 2011, PSC funding was used to conduct intensive studies to estimate Chinook escapement (fish > 59 cm ) for the entire basin using a variety of methods. These estimates were on average $23 \%$ higher than the traditional estimates based on expanding peak fish counts, but study estimates for 2005 and 2007 were nearly double the traditional estimates. Escapement was estimated using MR methodologies from 2002 to 2004, and in 2011; live-count AUC methodologies in 2005 and 2006; redd-based methodologies in 2007 and 2008; and genetic mark-recapture (GMR) methodologies in 2009 and 2010. Since 2011, a combination of physical MR of fish above the weir and redd count expansion for fish spawning below the weir have been used. A time series of expanded escapement estimates and further details for each year is now available on WDFW's Salmon Stock Inventory (SaSI) system (https://data.wa.gov/Natural-Resources-Environment/WDFW-Salmonid-Stock-Inventory-Population-Escapemen/fgyz-n3uk/data). The data graphed are total naturally spawning fish expanded from redd counts from the mouth of Mulholland Creek (RM 18.4) downstream to the Jeep Club Bridge (RM13.1). Escapements since 2014 have been less than the agency minimum natural escapement goal of 1000 (Figure 2.56).
Escapement Goal Basis: The Coweeman stock has no CTC-agreed goal. It is managed according to an abundance-based exploitation rate ceiling schedule for Lower Columbia River Tule Chinook salmon under ESA fishery consultation standards. The agency recovery goal is 3,600 with a maximum recovery exploitation rate determined by NOAA, and an interim minimum natural escapement goal of 1,000.

Agency Comments: Coweeman Tule stock is listed as threatened under the U.S. ESA.

Figure 2.56-Coweeman River tule fall Chinook salmon escapements, 1975-2020.

### 2.3.4.3.4 Lewis River Fall

Escapement Methodology: Most natural bright fall Chinook salmon production below Bonneville Dam occurs in the North Fork Lewis River. The Lewis River Wild stock is the main component of the Lower River Wild management unit for fall Chinook salmon, which also includes small amounts of wild production from the Cowlitz and Sandy river basins. In this report, the escapements and goal are for the Lewis River component. Peak weekly counts of live and dead fish in the 6.4 km area below Merwin Dam (river km 31.4) are expanded by a factor of 5.29 to estimate total spawning escapement (hatchery and wild). This expansion factor was derived from a carcass tagging and recapture study in 1976 (Mclsaac 1990) and was verified by studies from 1999 to 2001. Wild smolts have been coded-wire tagged since 1977.

Escapement Goal Basis: The escapement goal of 5,700 fall Chinook in the Lewis River was developed by Mclsaac (1990) based on spawner-recruit analysis of the 1964 to 1982 broods and CWT recoveries from the 1977 to 1979 broods. This analysis was updated by the CTC (1999) using brood years 1964 to 1991 and 5,700 was accepted as a biologically based goal.

Agency Comments: Lewis River escapements have been above the escapement goal since 1979, except for 1999, 2007-2009, and 2018. Since 2018, escapements have shown an impressive increase to over 25,000 (Figure 2.57).

Figure 2.57-Lewis River fall Chinook salmon escapements, 1975-2020.

### 2.3.4.4 Coastal Oregon

The North Oregon Coast (NOC) and Mid-Oregon Coast (MOC) Chinook salmon are aggregates with stocks migrating to SEAK and NBC AABM fisheries. With the adoption of the new PSC Chinook Model containing updated base period information, both NOC and MOC aggregates are now accounted for in PSC management.

### 2.3.4.4.1 North Oregon Coast

The NOC Chinook salmon production consists predominantly of naturally spawned, fallreturning fish, with an ocean-type life history. Adult spawning escapement is dominated by 4and 5-year-old fish with smaller proportions of 3 - and 6 -year-old fish. These Chinook salmon from the NOC aggregate are caught primarily in SEAK, NBC and in terminal fisheries.

Forecasts for the NOC aggregate are based on forecast models developed for each discrete stock, both indicator and non-indicator stocks. The aggregate forecast for NOC is the sum of the forecasts for the individual basins within the geographic range. Forecasting methods were developed in 2008 and are continually refined with each year's additional information. Prior to 2008, the aggregate forecast (and each of the indicator stock forecasts) was based on a running 3 -year average.

Stocks in the NOC aggregate are those salmon spawning from the Necanicum River in the north through the Siuslaw Basin in the south. Three escapement indicator stocks represent the production of NOC Chinook salmon: the Nehalem, Siletz, and Siuslaw stocks. Other stocks in the NOC aggregate include the Nestucca, Yaquina, Alsea, and Tillamook stocks. The Tillamook stock includes several substocks from the Kilchis, Miami, Trask, Tillamook and Wilson rivers.

All escapement indicators for the NOC aggregate have met their escapement goal this past year (Nehalem, Siletz and Siuslaw). Other basins within the aggregate (Tillamook, Yaquina and Alsea, ) have exhibited upturns in escapement from the lower escapements seen throughout the aggregate over the past two years. It is likely that the Siuslaw basin would not have met escapement goal had it not been for 2020 terminal fishery reductions. The Siuslaw basin did meet its goal for the first time since 2016.

### 2.3.4.4.1.1 Nehalem River

Escapement Methodology: Both historically conducted surveys and MR based calibrations, are expanded to represent available habitat (the historic agency methods), were used to estimate escapement in the Nehalem during the 2020 return year. Standard estimates were generated from peak abundance observed during surveys of historically walked standard index areas of known spawning habitat within the basin. These observations were then adjusted by estimates of the total available habitat, estimated observer bias, the total run encountered during the peak count, and the bias observed between these predefined surveys and other survey areas that were randomly selected. Figure 2.58 represents escapement estimates generated using historical agency methodologies which are directly comparable to the established escapement goal. Since the adoption of the Phase II base period PSC Chinook Model in 2019, escapement estimates based on calibration factors derived and directly tied to $M / R$ studies in this basin have been employed to provide for relatively accurate and precise assessments of this basin's adult Chinook escapement.
Escapement Goal Basis: The current point goal of 6,989 spawners was derived by Zhou and Williams (1999) and was based on assessments of escapement made through historical survey methodology.

Agency Comments: Methods of escapement estimation comparable to those used to generate the agreed-to escapement goal for the Nehalem indicate a 2020 escapement of 20,046 adult spawners. This is $287 \%$ of the current escapement goal. Based on multiple forecasting models, the Nehalem stock is forecasted to meet the escapement goal in 2021. ODFW is currently engaged in analysis from recent MR experiments to reconstruct historic estimates from peak survey counts, and to apply those estimates towards an updated escapement goal.

Figure 2.58-Nehalem River escapements of Chinook salmon, 1975-2020.

### 2.3.4.4.1.2 Siletz River Fall

Escapement Methodology: Standard estimates were generated from peak abundance observed in historically walked predefined areas of known spawning habitat within the basin. These observations were then adjusted by estimates of the total available habitat, estimated observer bias, the total run encountered during the peak, and the bias observed between these predefined surveys and other survey areas that are randomly selected. Escapement estimates generated using historical agency methodologies were used to develop the current escapement goal and are presented for comparison with that goal (Figure 2.59).

Escapement Goal Basis: The current point goal of 2,944 spawners is from Zhou and Williams (2000) and was based on assessments of escapement made through standard survey methodology.

Agency Comments: This stock has been studied with funds from the SSP to improve escapement estimation using MR methods. However, traditional methods of escapement estimation remain in place until MR -based estimates and a goal based on MR calibrated surveys is complete. The estimate derived from standard methods was 6,543 fall Chinook salmon ( $222 \%$ of goal) in 2020. Following a period of failing to meet escapement goals between 2007 through 2009, this stock has met its escapement goal each year since 2010. Terminal fisheries restrictions deployed in both 2019 and 2020 in response to sluggish escapement recoveries are not anticipated in the coming fishing year. This stock is forecasted to meet or exceed its escapement goal in 2021.

Figure 2.59-Siletz River fall escapements of Chinook salmon, 1975-2020.

### 2.3.4.4.1.3 Siuslaw River Fall

Escapement Methodology: Historically, standard surveys and updated estimates based on MR calibration factors were used to measure escapement in the Siuslaw basin during 2020.
Standard estimates were generated from observation of peak abundance in historically walked, predefined areas of known spawning habitat within the basin. These observations were then adjusted by estimates of the total available habitat, estimated observer bias, the total run encountered during the peak, and the bias observed between these predefined surveys and those that are randomly selected. These standard estimates are used to derive the current escapement goal and are used for comparison with that goal (Figure 2.60).

Escapement Goal Basis: The current point goal of 12,925 spawners was derived in 2000 by Zhou and Williams (2000) and was based on assessments of escapement made through standard survey methodology.

Agency Comments: Escapement in 2020 for the Siuslaw stock, estimated based on standard habitat expansion methods, was 14,384 adult spawners (111\% of the escapement goal). The MR- calibrated estimate was 4,430 adult spawners. The performance to goal was likely in large part due to terminal fisheries restrictions within the basin this past escapement year. The current escapement goal estimate was based on the standard escapement estimates, like other basins on the Oregon coast. Ultimately, a new goal should be developed from a calibrated historical data series. This stock is forecast to meet the current escapement goal in 2021 and consequently those terminal fisheries restrictions in place during the 2020 return year are not anticipated for the 2021 return year.

Figure 2.60-Siuslaw River fall escapements of Chinook salmon, 1975-2020.

### 2.3.4.4.2 Mid-Oregon Coast

The South Umpqua and the Coquille stocks are the two escapement indicator stocks for the MOC aggregate. This area is bounded by the Umpqua River on the north and the Elk River Basin on the south, and includes two additional major basins, the Coos and Coquille, and two small basins, Floras Creek and the Sixes River.

The MOC consists of a mixture of natural and hatchery-produced salmon, both of which return in the fall and follow an ocean-type life history. The largest age class proportions which normally contribute to spawning escapement are 3-and 4-year-old fish with smaller proportions of 5-and a very rare 6-year-old fish. These Chinook salmon are caught primarily in SEAK, NBC, Pacific Fishery Management Council (PFMC) fisheries and in terminal fisheries. Basins within this aggregate had suffered from an escapement downturn in the previous two years, with both S. Umpqua and Coquille basins exhibiting historically low abundance. Since 2018 these stocks have been rebuilding.

Forecasts for MOC stocks, except for the Elk River stock, are based on multiple forecasting models which are updated and re-assessed annually. Forecasts for the Elk River stock are based on projected survival rates of hatchery releases and recent proportions of wild adults in the aggregate return.

### 2.3.4.4.2.1 South Umpqua River Fall

Escapement Methodology: Until 2013, aerial spawning surveys for fall Chinook salmon had been conducted by the ODFW on both the South Umpqua River and Cow Creek since 1978; the surveys were started as part of Douglas County's mitigation plan for the construction and operation of Galesville Dam on upper Cow Creek.

However, following a 2013 crash that injured two ODFW employees and the pilot, ODFW aerial surveys were discontinued and methods changed. The new method involves a visual index of abundance that serves as an alternative to aerial survey counts. The visual index includes a sum of dead count from two spawning ground surveys within the South Umpqua drainage. Results from a calibration assessment of dead Chinook salmon to MR estimates indicated a strong correlation from two reaches in the basin. This strong relationship to the MR estimates allows for both the long-term redd count data and more contemporary sum of dead counts to correlate to known fish abundance. Figure 2.61 shows South Umpqua River escapement of fall Chinook salmon, 1978-2020.

Escapement Goal Basis: ODFW is currently engaged in analysis which will produce an escapement goal for this stock.

Agency Comments: Recoveries of CWTs from fall run Chinook salmon from the Umpqua River indicate that they are caught in PST fisheries. Budget constraints precluded the field work required for 2016 estimates. Funding for sampling in 2020 was secured, and the agency was able to generate an estimate for the 2020 return year. The 2020 escapement estimate is 2,443 adult Chinook salmon, which is about three times the escapement observed in the previous return year and similar to the reduced escapement observed in 2018. The South Umpqua return is forecast to continue to rebuild in the coming return year 2021.

Figure 2.61-South Umpqua River escapement of fall Chinook salmon, 1975-2020

### 2.3.4.4.2.2 Coquille River Fall

Escapement Methodology: MR-calibrated conducted surveys were used to measure escapement in 2020. Values presented in Figure 2.62 are based on values calibrated to MR estimates and may also be found in Appendix B12.

Escapement Goal Basis: ODFW is currently engaged in analysis which will produce an escapement goal for this stock.

Agency Comments: Methods based on MR-calibrated analysis yield continued recently lowbound trending adult escapement estimate of 794 Coquille Basin spawners in 2020.

Figure 2.62-Coquille River escapement of fall Chinook salmon, 1975-2020.

## 3. Stоск Status

### 3.1 Synoptic Evaluation of Stock Status

The following sections include graphics to display stock status information with spawning escapement on one axis and exploitation rate on the other. These synoptic plots display summary information for individual escapement indicator stocks. The figures present both the current status of stocks and the history of the stocks relative to PST management objectives. Information used in these figures includes (1) escapement data; (2) PSC-agreed MSY management objectives (or, in some cases, habitat model or agency escapement objectives that have yet to be agreed upon by the CTC); and (3) exploitation rates from related CWT indicator stocks to clearly summarize the performance of the stocks and fisheries management relative to established or potential goals.

The plots resemble those presented for groundfish in Garcia and De Leiva Moreno (2005). A general depiction of the plots with three reference lines is provided in Figure 3.1. The plots show the exploitation rate ( $x$-axis) and escapement abundance ( $y$-axis) of each stock for available years of data. There are three reference lines, a vertical one for exploitation rate (UMSY) and two horizontal ones for escapement abundance. The definition of reference points for PST Chinook salmon stocks is based on the management objectives (escapement and exploitation rate) identified in the 2019 Agreement. For stocks with point escapement goals, the upper reference line is $S_{\text {MSY }}$, and the lower reference line is $0.85 * S_{\text {MSY }}$. For stocks with escapement objectives defined as ranges (SEAK, TBR, and the Harrison River), the upper reference line is the lower bound of the escapement range and the lower reference line is $85 \%$ of the lower bound. The exploitation rate reference line ( $\mathrm{U}_{\text {MSY }}$ ) is the exploitation rate at $\mathrm{S}_{\text {MSY }}$ for stocks with escapement objectives.

Figure 3.1-Precautionary plot for synoptic evaluations of PST Chinook salmon stocks.

The three reference lines produce five zones in the synoptic plots. The green area (Safe Zone) in Figure 3.1 represents a healthy stock status where fishing is below $U_{\text {MSY }}$ and the concurrent stock spawning abundance is above the escapement goal. The red area (High Risk) represents a stock in which exploitation is above $U_{\text {MSY }}$ and escapement abundance is below the escapement goal. The two yellow zones (High Escapement High Exploitation, Low Escapement Low Exploitation) represent situations in which the stock could be in danger of falling into an area of conservation concern; in the upper right (High Escapement High Exploitation), escapement is at a healthy level, but fishing mortality is above the U MSy limit, and in the lower left (Low Escapement Low Exploitation), fishing is occurring below the $U_{\text {MSY }}$ limit but the population failed to attain a desired minimum escapement. The cross-hatched region is the escapement buffer zone, where fishing mortality is below UMSY but escapement is also slightly low.

Exploitation rates used in the synoptic plots are one of the following: calendar year exploitation rates, preterminal cumulative mature-run equivalent (MRE) exploitation rates, or total (preterminal and terminal) cumulative mature-run equivalent exploitation rates. Total cumulative mature-run equivalent exploitation rates are not used when there is a terminal fishery targeting a hatchery indicator stock because the terminal exploitation will differ from that on the wild stock being represented. The ages used in the escapement and exploitation rate calculations are not the same for each stock and typically exclude age 2 for ocean-type stocks and age 3 for stream-type stocks. See Table 3.1 for parameter definitions.

Calendar year exploitation rates, $C Y E R_{C Y}$, are computed as

$$
\text { CYER }_{C Y}=\frac{\text { OceanMorts }}{C Y}+\text { TermMorts }_{C Y}{ }_{\left(\text {OceanMorts }_{C Y}+\text { TermMorts }_{C Y}+\text { OESC }_{C Y}\right)}
$$

Cumulative mature-run equivalent exploitation rates, $C M R E E R_{C Y}$, are computed as

$$
\text { CMREER }_{C Y}=1-\left(\frac{O E S C_{C Y}}{P E S C_{C Y}}\right)
$$

where

$$
O E S C_{C Y}=\sum_{a=s t a r t a g e}^{\text {maxage }} O E S C_{C Y, a}
$$

and

$$
P E S C_{C Y}=\sum_{a=s t a r t a g e}^{\text {maxage }} P E S C_{C Y, a}
$$

where

$$
\text { PESC }_{C Y, a}=\frac{\text { oESC }_{C Y, a}}{\text { CumSurvRte }_{C Y-a, a}} .
$$

When computing total (preterminal and terminal) mature-run equivalent exploitation rates, the cumulative survival rate is computed for each age in a brood year as

$$
\text { CumSurvRte }_{B Y, a}=\text { TermSurvRte }_{B Y, a} * \prod_{i=s t a r t a g e}^{a} \text { PreTermSurvRte }_{B Y, i} .
$$

When computing preterminal mature-run equivalent exploitation rates, the cumulative survival rate is computed for each age in a brood year as

$$
\text { CumSurvRte }_{B Y, a}=\prod_{i=\text { startage }}^{a} \text { PreTermSurvRte } e_{B Y, i} .
$$

The preterminal harvest rates for each age in a brood year are computed as

$$
\text { PreTermHR }_{B Y, a}=\frac{\text { OceanMorts }_{B Y, a}}{\text { CohortSizeANM }_{B Y, a}} .
$$

The preterminal survival rates for each age in a brood year are computed as

$$
\text { PreTermSurvRte }_{B Y, a}=1-\text { PreTermH }_{B Y, a} .
$$

Table 3.1-Parameter definitions for all equations used to estimate CY exploitation rates and cumulative mature-run exploitation rates.

| Parameter | Description |
| :--- | :--- |
| $a$ | Age |
| $B Y$ | Brood year |
| CY | Calendar year |
| CMREER $_{C Y}$ | Cumulative mature-run equivalent exploitation rate for calendar year $C Y$ |
| CohortSizeANM $_{B Y, a}$ | Cohort size after natural mortality for brood year $B Y$ and age $a$ |
| CumSurvRte ${ }_{B Y, a}$ | Cumulative survival rate for brood year $B Y$ and age $a$ |
| CYER $_{C Y}$ | Calendar year exploitation rate for calendar year $C Y$ |
| OceanMorts $_{B Y, a}$ | Ocean mortalities for brood year $B Y$ and age $a$ |
| OESC $_{C Y}$ | Observed escapement for calendar year $C Y$ |
| OESC $_{C Y, a}$ | Observed escapement for calendar year $C Y$ and age $a$ |
| PESC $_{C Y}$ | Potential escapement for calendar year $C Y$ |
| PESC $_{C Y, a}$ | Potential escapement for calendar year $C Y$ and age $a$ |
| PreTermHR $_{B Y, a}$ | Pre-terminal harvest rate for brood year $B Y$ and age $a$ |
| PreTermSurvRte $_{B Y, a}$ | Pre-terminal survival rate for brood year $B Y$ and age $a$ |
| TermMorts $_{C Y}$ | Terminal mortalities for calendar year $C Y$ |
| TermSurvRte $_{B Y, a}$ | Terminal survival rate for brood year $B Y$ and age $a$ |

Data necessary to plot the stock trajectories are available for most escapement indicator stocks (Table 3.2). Most escapement indicator stocks have companion exploitation rate indicator stocks that are assumed to reflect the exploitation rates in pre-terminal areas. Exploitation rate data may not be available for some stocks in the period 1975 to 1984, so plots may show a different start year. Similarly, there are some stocks for which data are unavailable in the most recent year, particularly in the Southern U.S., because sport fishery catches that are needed for CWT expansions are generally lagged by one year. With suitable assumptions about terminal area fisheries, the total exploitation rates on stocks can be estimated. Most areas along the coast have escapement indicator stocks. Notable exceptions are the Upper Strait of Georgia (UGS) area the WCVI area and the Fraser River early stocks (spring and summer). Regionspecific synoptic evaluations of Chinook salmon stocks are presented in Section 3.2. The stock-
specific synoptic plots presented in this section are grouped by relevant Treaty periods: preTreaty, 1985-2008, 1999-2008, 2009-2018, and 2019-2028.

Table 3.2-Summary of information available for synoptic stock evaluations.
Note: Shaded rows indicate stocks that cannot be evaluated because of data gaps.

[^3]${ }^{4}$ Two types of exploitation rates were used: cumulative mature-run equivalents (CMRE) which are based on CWT recovery data and calendar year (CY) which are based on actual stock assessment data gathered annually.
${ }^{5}$ Stocks with an escapement goal range use $85 \%$ of the lower bound.
${ }^{6}$ Kitsumkalum is not an attachment I stock.
${ }^{7}$ Agency escapement goal has the same status as CTC-accepted escapement goal for implementation of Chapter 3.
${ }^{8}$ Natural origin spawners.
${ }^{9}$ CWT indicator stocks and fishery adjustments described in CTC (2016), CTC (2019; ISBM Subgroup Technical Note) and CTC (2021).
${ }^{10}$ Revised habitat-based values that also include an adjustment for the lower than average fecundity of this stock.

A synoptic summary plot for 22 stocks with 2019 data shows that most stocks were in the safe zone (exploitation below U Usy and escapement above Smsy; Figure 3.2). One stock, the Siuslaw, was in the high-risk zone. Two stocks, Atnarko and Stikine, were in the buffer zone. Three stocks were in the low escapement and low exploitation zone: Taku, Nicola, and Harrison. No stocks experienced exploitation above $U_{\text {MSY }}$ with escapements exceeding $S_{\text {MSY }}$.

Figure 3.2-A synoptic summary by region of stock status for stocks with escapement and exploitation rate data in 2019.

Note: Escapement and exploitation rate data were standardized to the stock-specific escapement goal and $U_{M S Y}$ reference points.

### 3.2 Regional Trends and Profiles

### 3.2.1 Southeast Alaska: Situk, Chilkat, and Unuk Rivers

Recent declines in Chinook salmon productivity and abundance are widespread and persistent throughout Alaska. Available run abundance data indicate significant declines were first fully detected in 2007 from a persistent decline in productivity that began with returns from brood year 2001. Run abundance data available from 11 stocks in Southeast Alaska show substantial variability and moderate to no coherence among stocks prior to 2004 (Figure 3.3). This is consistent with downward trends in productivity and similar declines of SEAK Chinook salmon stocks.

The SEAK stocks exhibit two consistent rearing behaviors. Outside-rearing behavior includes rearing in the Gulf of Alaska and Bering Sea after leaving the freshwater environment. Insiderearing behavior involves rearing in the nearshore environment of SEAK for a significant amount of time. The Situk stock is an outside-rearing stock and the Chilkat and Unuk stocks are inside-rearing. However, CWT recovery data suggest at least a small proportion of the insiderearing fish exhibit some outside-rearing behavior. The decline in productivity is far reaching, extends beyond SEAK, and has affected most Alaska Chinook stocks.

Figure 3.3-Average of standardized deviations from average run abundance for 11 stocks of Chinook salmon in Southeast Alaska

Includes: the Situk, Alsek, Chilkat, Taku, King Salmon, Andrews, Stikine, Unuk, Chickamin, Blossom and Keta in Southeastern Alaska.

The Situk stock has failed to meet the escapement goal six times since 2009 (Figure 3.4). Over the recent decade, this stock has demonstrated poor performance like the other SEAK escapement indicator stocks. This failure cannot be explained by fishery impacts; they have been extremely low, with a recent 10-year average calendar year exploitation rate of $8 \%$. Harvests mostly occur in-river or in the estuary and detailed catch accounting programs enumerate most harvest, yielding CY estimates of exploitation. This stock is outside-rearing and
is not exposed to SEAK harvest before maturation. Calendar year exploitation rates for the Situk stock have never exceeded the U USy threshold of $81 \%$ (Figure 3.4). Generally, poor runs and escapement result primarily from decreased productivity, and mirror the very low productivity of other Alaskan stocks. Conservation measures have been in place to reduce harvests in the effort to pass as much of the run to escapement as possible and these efforts will continue in 2021.

Figure 3.4-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement for large (greater than 659 mm MEF in length) Situk River Chinook salmon, 1976-2020.

Chilkat River Chinook salmon return to northern SEAK and are mostly inside-rearing. The Chilkat River stock failed to achieve its escapement goal six times since 2009. The Chilkat River is located at the northern end of Lynn Canal; gillnet and sport fisheries in the region are managed to conserve this stock.

A CWT program has been in place since the 1999 brood year to estimate the harvest of Chilkat Chinook salmon. Recoveries of CWTs indicate some age-4 Chilkat fish are harvested while rearing in SEAK, primarily in the net fisheries. Most of the harvest is mature fish from sport and commercial troll and drift gillnet fisheries in SEAK. In general, exploitation rates on the Chilkat stock are some of the lowest observed in the region, with a recent 10-year average CY exploitation rate of $13 \%$, well below the $U_{\text {MSy }}$ threshold reference value of $40 \%$ (Figure 3.5).

Smolt abundance and survival have been estimated for the Chilkat stock since the 1999 brood year. Since the 2008 brood year, there has been no apparent trend in freshwater survival; however, marine survival has generally been below average for recent broods (Figure 3.6). Below average marine survival has negatively affected abundance; continued low exploitation rates are needed to achieve the escapement goal until productivity improves.

Figure 3.5-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement for $\geq 0 c e a n ~ a g e-3 ~ C h i l k a t ~ R i v e r ~ C h i n o o k ~ s a l m o n, ~$ 2004-2020.

Figure 3.6-Freshwater and marine survival indices (standardized to a mean of zero) for the Chilkat River stock of Chinook salmon, 1999-2013 brood years.

The Unuk River flows into Behm Canal in southern SEAK and Chinook salmon from the Unuk River are mostly inside-rearing. Similar to other SEAK indicator stocks, escapements to the Unuk River were below the escapement goal six times since 2009. There are no Chinook salmon fisheries in freshwater or in most marine waters of the adjacent Behm Canal. Most southern SEAK stocks are harvested at below threshold rates while rearing and maturing, and they are not harvested in terminal areas due to management closures.

A CWT program was implemented beginning with the 1992 brood year to estimate harvest in mixed-stock fisheries. In sharp contrast to other SEAK stocks, exploitation rates for the Unuk stock have been high in recent years, with a recent 10-year average CY exploitation. Some Unuk Chinook salmon are caught while rearing in SEAK, but most of the harvest is mature fish. Exploitation rates on this stock have historically averaged about one-half of the threshold reference value. However, during the recent period of poor production, rates have been the highest on record, including an over the $U_{\text {MSy }}$ threshold exploitation rate of $72 \%$ in 2012 (Figure 3.7). As a result, additional domestic management measures have been imposed to reduce exploitation rates and pass more fish to escapement.

Figure 3.7-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement of large (greater than 659 mm MEF in length) Unuk River Chinook salmon, 1997-2020.

Estimates of smolt abundance and survival are available beginning with the 1992 brood year. Freshwater survival has, for the most part, shown no apparent pattern. The 2003 and 2005 brood year freshwater survival estimates were some of the lowest on record. However, high freshwater survival occurred in 2006 and in 2012. Unfortunately, freshwater, and marine survival have shown an inverse relationship in the time series. The highest freshwater survival for the 2012 brood year coincided with the lowest marine survival, while the highest marine survival for the 2005 brood year coincided with the lowest freshwater survival. Marine survival was near-average and showed high inter-annual variability over the 1991 to 2005 brood years. However, the 2006 to 2013 brood years exhibited some of the lowest marine survivals over the range of data (Figure 3.8).

Figure 3.8-Freshwater and marine survival indices (standardized to a mean of zero) for the Unuk River stock of Chinook salmon, 1992-2013 brood years.

### 3.2.2 Transboundary Rivers: Alsek, Taku, and Stikine Rivers

Transboundary stocks include Chinook salmon originating from the Alsek, Taku, and Stikine rivers. The Alsek River stock has failed to achieve the lower bound of the escapement goal four times over the most recent 10-year period, and the Taku and Stikine river stocks have failed to achieve the lower bound of the goal six and five times, respectively, in the same time period, including the most recent five years.

The recent failure of the Alsek stock cannot be solely explained by over-harvest, as the Alsek River stock has one of the lowest exploitation rates for a Chinook salmon stock on the Pacific Coast, averaging 10\% over the most recent 10-year period. All known harvests occur inriver in the U.S. and Canada and detailed catch accounting and age, sex, length, and genetic sampling programs are in place for U.S. harvests and for sport and Aboriginal harvests in Canada. Most samples are taken at a weir across the Klukshu River, an index tributary of the Alsek River. Similar to Situk River Chinook salmon, the Alsek stock is not exposed to SEAK fisheries while rearing. Exploitation rates have never approached the $U_{\text {MSY }}$ threshold of 58\% (Figure 3.9). Poor runs and escapement are likely the result of decreased productivity and mirror other Alaskan stocks that rear in the Gulf of Alaska and Bering Sea. During this period of poor production, management measures have been in place to reduce harvests in both countries in the effort to pass as much of the run to escapement as possible.

Figure 3.9-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement $\geq$ ocean age-2 Alsek River Chinook salmon, 1976-2020.

The Taku and Stikine river stocks have also experienced reduced productivity and changing age composition in recent years, which has affected forecasting accuracy. Preseason forecasts are developed for each of these stocks by December 1 per obligations specified in Chapter 1 of Annex IV. During years of surplus production, the preseason forecasts trigger directed Chinook salmon fisheries in the U.S. and Canada and in-season estimates are used to refine fishery management. In recent years, forecasts have overestimated the run size. To account for this, forecasts have been adjusted by the five-year average percentage error; this method has better estimated run size. Since 2009, the escapement goals for these two stocks have been missed six (Taku) and five (Stikine) times, including all years since 2016.

Taku and Stikine River stocks rear in the Gulf of Alaska and Bering Sea and have minimal exposure to SEAK fisheries as immature fish; almost all harvest consists of mature fish. Both stocks are harvested in terminal marine sport fisheries and incidentally in U.S. marine and Canadian inriver traditional sockeye salmon gillnet fisheries that take place near the end of the Chinook salmon runs. Both stocks are also caught outside of the terminal districts in commercial spring troll and net fisheries and in outside sport fisheries. Most harvest takes place inriver and in terminal areas, and detailed genetic stock identification programs are in place to identify Taku and Stikine Chinook salmon in mixed stock marine fisheries. These programs, when coupled with the assessment methods described in McPherson et al. (2010) for CYs 1977 to 2007 for the Taku River stock and in Bernard et al. (2000) for CYs 1981 to 1997 for the Stikine River stock, have been used to provide CY harvest estimates since 2005.

Exploitation rates for the Taku River have never exceeded the $U_{\text {msy }}$ threshold of 59\% (Figure 3.10). Calendar year exploitation rates averaged $15 \%$ over the most recent 10-year period; escapements failed to meet the escapement goal in six of those years (2013, 2016-2020). Between 1975 and 2010, the average exploitation rate was 15\%, and escapements were below the goal for five years.

Figure 3.10-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement for large (greater than 659 mm MEF in length) Taku River Chinook salmon, 1975-2020.

Stikine River Chinook salmon CY exploitation rates averaged 22\% over the most recent 10-year period, and escapements failed to meet the escapement goal consecutively from 2016 through 2020 (Figure 3.11). Substantial directed fishing occurred from 2005 to 2008 with exploitation rates averaging 47\%, which was over the $U_{\text {MSy }}$ threshold value of 42\%; however, the escapement goal was achieved in each of those years. Prior to 2005, the average exploitation rate was $20 \%$, and escapements were above the goal in all but seven years.

Exploitation rates on Alsek, Taku, and Stikine river stocks will need to remain low until production improves.

Chinook salmon smolt abundance and survival have been monitored for the Taku River stock since the 1991 brood year. Freshwater survival has been above the long-term average six out of the recent ten brood years. However, marine survival has undergone cycles throughout this period and the most recent ten brood years have all been below average (Figure 3.12).

Figure 3.11-Calendar year exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement for large (greater than 659 mm MEF in length) Stikine River Chinook salmon, 1975-2020.

Figure 3.12-Freshwater and marine survival indices (standardized to a mean of zero) for the Taku River stock of Chinook salmon, 1991-2013 brood years.

Smolt abundance and survival have been monitored for Stikine River Chinook salmon since the 1998 brood year. Freshwater survival over this time period has been declining and marine survival has also been below the long-term average six out of the recent ten brood years (Figure 3.13).

Figure 3.13-Freshwater and marine survival indices (standardized to a mean of zero) for the Stikine River stock of Chinook salmon, 1998-2013 brood years.

### 3.2.3 Canadian Stocks

### 3.2.3.1 Northern British Columbia: Kitsumkalum River

The Skeena River is an escapement indicator stock in NBC and it does not have a PSC-agreed escapement goal. The Kitsumkalum River is a tributary of the Skeena River and is the CWT indicator stock for the Skeena River. High quality MR escapement data have been collected for Kitsumkalum River Chinook salmon annually since 1984. The method for determining escapement estimates was revised in 2019 to use open population models (Winther et al. In prep.). Revised escapement estimates from the open population models were lower in most years than previous estimates, as were the stock-recruit parameters (e.g. preliminary $\mathrm{S}_{\text {MSY }}=$ $5,235)$. Prior to 2019 the MR escapement estimates were produced using the Petersen method. Under the closed population models, McNicol (1999) estimated the stock-recruit relationship ( $S_{\text {MSY }}=8,876$ ), that was updated by Parken et al. (2006) ( $S_{M S Y}=8,621$ ). Spawning escapements have exceeded $\mathrm{S}_{\text {MSY }}$ reference line in all years but two. In 1997 the stock was in the buffer zone and in 2017 the stock was in the low escapement and low exploitation zone.

This stock has had very low levels of enhancement relative to the CWT indicator stock targets. The mean proportion of hatchery fish in the returns was $5.0 \%$ and ranged from $0.5 \%$ in 1988 to 15.4\% in 2018.

Early marine survival of Kitsumkalum Chinook has ranged from $0.14 \%$ to $1.95 \%$ and averaged $0.79 \%$ (Figure 3.14). Survival for the last complete brood (2014) was $0.20 \%$. The mature-run equivalent exploitation rates have been below the threshold reference line $\left(U_{\text {MSY }}=0.626\right)$ in all years (Figure 3.15).

Figure 3.14-Marine survival index (standardized to a mean of zero) for the Kitsumkalum River stock of Chinook salmon, 1979-2016 brood years.

Note: Brood year 1982 was not represented by CWTs; thus no datum is available.

Figure 3.15-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Kitsumkalum River stock of Chinook salmon, 1985-2020.

### 3.2.3.2 Central British Columbia: Atnarko River

The Central BC model stock group includes the Wannock, Chuckwalla-Kilbella and Atnarko escapement indicators. Currently, only the Atnarko has an escapement goal recognized in the new Agreement. The Atnarko River was added as an exploitation rate indicator stock in Area 8
in 2012 (Vélez-Espino et al. 2011) with MR escapement estimates produced annually (VélezEspino et al. 2010). These estimates were used to calibrate the time series of existing carcass count based escapement estimates and broodstock CPUE back to 1990 based on a generalized linear model approach (Vélez-Espino et al. 2014).

This stock has had a moderate level of enhancement relative to the CWT indicator stock targets (mean enhanced contribution $=39 \%$, range: $13-69 \%$, run years 1990-2020). The largest hatchery contributions occurred in in 1996 and 2015 with $67 \%$ and $69 \%$, respectively, whereas the lowest (13\%) took place in 2008. Increases in hatchery contribution during the early 2010s were partly due to the implementation of a yearling-release strategy in addition to the customary subyearling releases. Adjustments are made to escapement estimates to remove hatchery fish in order to make inferences for non-enhanced stocks in Central B.C. (Vélez-Espino et al. 2014). A stock-recruitment relationship has not yet been generated; however, a habitatbased estimate of $\mathrm{S}_{\text {MSY }}$ (Parken et al. 2006) of 5,009 large wild adults has been developed for Atnarko Chinook salmon (Vélez-Espino et al. 2014).

The average early marine survival (i.e., age-2 cohort survival) of Atnarko Chinook salmon is 2.26\% (for complete brood years 1986-2015), with an increasing survival index from brood year 1986 to brood year 1991, and remaining below average for most years from brood year 1992 up to brood year 2008 (Figure 3.16). For brood years 2009-2012, marine survival increased to a level comparable to that achieved for brood year 1990 and reached the highest recorded level (6.1\%) for brood year 2011. Survival rates were below average for the 2013 and 2014 broods, and close to the time series average for the 2015 brood.

Figure 3.16-Marine survival index (standardized to a mean of zero) for subyearling releases of the Atnarko River stock of Chinook salmon, 1986-2017 brood years. There were no CWT releases for brood years 2003 and 2004.

Estimates of total large adults (wild and hatchery, excluding jacks) have exceeded 10,000 fish in most years except in 1997 and 2007-2012 period when adult escapement reached its lowest point (4,622; Figure 3.17). However, escapement estimates for large wild adults have been below the S MSY goal of 5,009 fish in 1997, 2012, and 2019 and below the 0.85 S MSY threshold of 4,258, in 1997 and 2012 (Figure 3.18). Since mature-run equivalent (MRE) exploitation rates
have been below the threshold reference line in all years, this stock has been in the safe zone for most years.

Figure 3.17-Time series of Atnarko Chinook escapement integrating the calibrated values from the best Generalized Linear Model and best Maximum Likelihood estimates for years with mark-recapture studies (2001-2003 and 2009-2019).
Note: The horizontal dashed line shows the habitat-based escapement goal of 5,009 large adults.

Figure 3.18-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Atnarko River stock of Chinook salmon, 1990-2020.
Note: Spawning escapement excludes jacks to be consistent with the units represented by the $S_{\text {msy-based }}$ escapement goal.

### 3.2.3.3 Lower Strait of Georgia: Cowichan River

The Lower Strait of Georgia natural stock group includes the Cowichan River and Nanaimo River escapement indicators. Currently, only the Cowichan has a PSC-agreed escapement goal, and an estimated stock-recruitment relationship (Tomkins et al. 2005). The Cowichan River is an exploitation rate indicator stock with a high level of enhancement (mean enhanced contribution $=22 \%$ ) for years 1982-2020 (Figure 3.19), with the largest contribution in 2002 (62\%). Escapement estimates are produced by counting fence (weir) and MR methods. A habitat-based estimate of $S_{\text {MSy }}$ is available for the Nanaimo River; however, the exploitation rate indicator monitoring program was discontinued after brood year 2004.
Marine survival was generally above the mean for twelve brood years 1985, 1987 to 1994, and 2009 to 2011. Fourteen brood years were below the mean from 1995 to 1997, 1999 to 2003, 2005-2008 and 2012 to 2013. Two brood years were slightly above average in 1998 and 2014, and one brood year was slightly below average in 2015 (Figure 3.20). Similarly, the mature-run equivalent exploitation rates were above the threshold reference line in most years from 19851998. Escapements were below SMSY between 1997 and 2015 and exceeded SMSY from 2016 to 2020 (Figure 3.21). The stock has rarely been in the safe zone of the synoptic plot, only twice during the last 33 years, with most of the recent years in the high risk zone. However, in 2019 and 2020, the stock appears to be approaching the safe zone with exploitation rates at the upper MSY. The stock experiences the highest exploitation of the stocks examined in Section 3.

Figure 3.19-The percentage of first generation hatchery-origin Chinook salmon in the Cowichan River adult spawning population, 1982-2020.

Figure 3.20-Marine survival index (standardized to a mean of zero) for the Cowichan River stock of Chinook salmon, 1985-2017 brood years. Brood years 1986 and 2004 were not represented by CWTs, thus no data are available.

Figure 3.21-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Cowichan River stock of Chinook salmon, 1988-2020.

### 3.2.3.4 Fraser River Stocks

Within the Fraser River, three of five escapement indicator stocks are currently represented by exploitation rate indicator stocks. The Fraser River spring run age 1.2, Fraser River summer run
age 0.3, and Fraser River late run age 0.3 are represented by the exploitation rate indicator stocks at the Nicola, Lower Shuswap, and Harrison rivers, respectively. Fraser River spring run age 1.3 and Fraser River summer run age 1.3 are not currently represented by CWT indicator stocks.

### 3.2.3.4.1 Fraser River Spring Run Age 1.2: Nicola River

The Fraser River spring run age 1.2 stocks are small-bodied, early-maturing stocks that spawn in tributaries to the Lower Thompson River, and Louis Creek in the North Thompson River. The Nicola River is an exploitation rate indicator stock that has escapement estimates produced using MR methods. Currently, there are no CTC-agreed escapement goals for this group. Harvest occurs almost exclusively during the return migration while passing through Juan de Fuca and Johnstone Straits and Fraser River fisheries. Estimated escapements declined steeply between 2003 and 2009 and have remained low; currently this is a stock group of concern for Canadian fishery planning, and is being assessed by COSEWIC and SARA. This stock has had a moderate level of enhancement (mean enhanced contribution 30\%, years 1987-2020, range 479\%), which influences its representativeness for stocks in the stock group (Figure 3.22).

The threshold reference lines in Figure 3.23 were estimated from habitat-based methods (Parken et al. 2006). The Nicola River stock has been in the low escapement and low exploitation zone of the synoptic plot since 2009, which corresponds to a period of low productivity for many Chinook stocks (Dorner et al. 2018).

Figure 3.22-The percentage of first generation hatchery-origin Chinook salmon in the Nicola River escapement, 1987-2020.

Figure 3.23-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Nicola River stock of Chinook salmon, 1995-2020.

Survival decreased steeply starting with the 2000 brood (2002 ocean entry) and subsequently have remained at or below average, with the modest exception of the 2006 brood ( 2008 ocean entry; Figure 3.24). The very low survival for the 1992 brood year was caused by a Myxobacteria infection at Spius hatchery, and the survival for the 1994 brood year was affected by high pre-spawn mortality in 1998 (not measured).

Figure 3.24-Marine survival index (standardized to a mean of zero) for the Nicola River stock of Chinook salmon, 1985-2016 brood years.

### 3.2.3.4.2 Fraser River Summer Run Age 0.3: Lower Shuswap River

The Fraser River summer run age 0.3 stocks are far north migrating, ocean-type stocks that spawn in Maria Slough (Lower Fraser River), the Lower Thompson River, and South Thompson River and tributaries. Marine survival has been fluctuating since 1984; however, many of the brood years since 2000 have experienced below average survivals (Figure 3.25). These fish remain on the continental shelf for their entire marine residence and are vulnerable to harvest throughout that period and during return migration, in both marine and Fraser River fisheries. Annual escapements to this stock group increased from about 25,000 through the 1980s to more than 85,000 between 2006 and 2011. Since then, escapements have been mostly near or greater than 85,000 , peaking in 2015 at an estimated 180,000 fish, and declining steeply in 2012 to about 48,000 fish and 2018 to about 46,000 fish. Escapements to this stock group have returned to a high level in 2019 and 2020, with approximately 148,000 returning in 2020.

The Lower Shuswap River is an exploitation rate indicator stock that has had escapement estimates produced using MR methods since 2000. The PSC adopted a management objective in the 2019 Agreement, which is the same value as the agency goal, and was estimated from habitat-based methods (Parken et al. 2006). The Lower Shuswap River has had a low to moderate level of enhancement (mean enhanced contribution 11\%, years 1987-2020), which influences its representativeness for non-enhanced stocks in the stock group (Figure 3.26). The Lower Shuswap CWT stock has been below the UMsy reference line in the synoptic plot in all but five years. Since implementation of the 2009 Agreement, ten years were in the safe zone and two years (2012 and 2016) were in the low escapement and low exploitation zone.

Figure 3.25-Marine survival index (standardized to a mean of zero) for the Lower Shuswap River stock of Chinook salmon, 1978-2017 brood years.

Figure 3.26-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Lower Shuswap River stock of Chinook salmon, 1981-2019.

### 3.2.3.4.3 Fraser Late Run Age 0.3: Harrison River

The Fraser late stocks are white-fleshed fall-run Chinook salmon, originating from the Harrison River downstream of Harrison Lake in the Lower Fraser River. Juveniles migrate to the Fraser estuary immediately after emergence and remain in the estuary area for up to six weeks before moving into the Strait of Georgia. Their ocean distribution is principally in the Salish Sea, WCVI, and Coastal Washington, where they are vulnerable to fisheries throughout their ocean residence. From 1984 to 2020, the enhanced contribution to this stock has averaged 4\% (range: $0-17 \%$ ). Marine survivals have been mostly below average since 1990 (Figure 3.27). Spawning escapements were below the goal range for nine of the past twelve years (Figure 3.28). The synoptic plot shows the stock with exploitation rates higher than the reference line in the majority of years from 1984 to 1998, with two years in the high risk zone and only one year in the safe zone. Cumulative exploitation rates were reduced under the 1999 Agreement, with most years having exploitation rates less than $U_{\text {msr. }}$ Exploitation rates were further reduced under the 2009 Agreement and exploitation rates have been below the reference line; however, only three years have been in the safe zone since 2009. The recent low escapements and low exploitation rates correspond with a period of low productivity for many Chinook stocks (Dorner et al. 2018). The Harrison River fall-run Chinook stock was assessed as "Threatened" by COSEWIC (2018).

Figure 3.27-Marine survival index (standardized to a mean of zero) for the Harrison River stock of Chinook salmon, 1981-2017 brood years. No data are available for brood year 2004.

Figure 3.28-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Harrison River stock of Chinook salmon, 1984-2019.

### 3.2.4 Puget Sound, Coastal Washington, Columbia River, and Coastal Oregon Stocks

### 3.2.4.1 Puget Sound

Puget Sound stocks are a mixture of natural- and hatchery-origin production of spring run and summer/fall run fish that influences both the fisheries within Puget Sound, and escapement to the spawning grounds. The hatchery stocks contribute to terminal fisheries and in some cases many hatchery strays escape to the spawning grounds. Consequently, historic patterns of wild Puget Sound Chinook salmon abundance may be obscured because of the interaction of hatchery- and natural-origin production in the fishery and escapement accounting. Hatchery programs in Puget Sound have annually released between about 23 million (1976) to over 56 million (1989) Chinook salmon (Figure 3.29). Since Puget Sound Chinook salmon were listed as threatened under the ESA in 1999, hatchery production has averaged about 33 million releases annually. Although Puget Sound hatchery programs historically emphasized production for fisheries alone, many of today's programs are also associated with endangered species recovery or wild broodstock CWT indicator programs. The harvest rate in terminal fisheries for these stocks has generally declined from between $40 \%$ and $60 \%$ through the mid-1980s to about $10 \%$ at the time of listing under the ESA in 1999. In most years, the majority of the terminal fishery harvest has depended on the status of Green River Chinook salmon and to a lesser extent on Skagit River fish. Directed terminal fisheries do not occur on Snohomish River, Stillaguamish River, and Lake Washington Chinook salmon. Terminal harvest data for 2020 have not been reviewed by co-managers, although indications are that overall Puget Sound terminal catches were lower than those in 2019.

Spring run stocks in Puget Sound exhibit both ocean-type (age-0 fingerling outmigrants) and stream-type (age-1 yearling outmigrants) life histories. Key spring stocks are the CTC escapement indicators in the Nooksack and Skagit rivers, as well as the White River (CWT indicator), with associated hatchery programs in each. Escapement in the Nooksack River is predominately hatchery-origin fish, whereas on the Skagit River, hatchery-origin fish are rarely seen in the spawning areas. The majority of Chinook salmon production from Puget Sound is comprised of summer/fall run ocean-type stocks. Skagit River summer/fall Chinook salmon is the largest stock in Puget Sound, and consists almost exclusively of natural-origin fish. The Skagit and Stillaguamish rivers have CWT exploitation rate indicator stocks but only Stillaguamish has a supplementation program that uses broodstock collected from the spawning grounds. Basins with large hatchery programs include the Snohomish and Green River CTC escapement indicators as well as the Samish, Puyallup, Nisqually and Skokomish rivers. In addition, net-pen programs in Bellingham and Tulalip bays release large number of juvenile Chinook salmon.

Figure 3.29-Chinook salmon released from Puget Sound hatcheries.

Estimates of total production for the Puget Sound CTC escapement indicator stocks have not been made in part because of the lack of long-term representative tag groups for the natural stocks (except Green River). The trend in the escapement of Puget Sound summer/fall CTC escapement indicator stocks is driven primarily by the status of Skagit River summer/fall stocks. In most years, the abundance of Skagit River fish is higher than the sum of the escapements of other Puget Sound CTC indicator stocks. This is especially true when the escapement of Skagit River summer/fall Chinook salmon averaged 17,900 from 2000 to 2006 and exceeded 20,000 from 2004 to 2006. For the period of 1975 to 2018, the aggregate escapement of Puget Sound summer/fall indicator stocks ranged from a low of about 10,300 in 2011, to a high of 45,000 in 2004 (Figure 3.30). The preliminary aggregate escapement was 20,400 in 2020, which is similar to the long-term average. As part of the 2019 Agreement, escapement goals were included in Attachment I for the Skagit spring and Skagit summer/fall stocks.

Figure 3.30-Escapement and terminal fishery harvest for the aggregate of Puget Sound summer/fall Chinook salmon PSC escapement indicator stocks.

Note: Terminal harvest not available for last year.
The long-term escapement trends for Puget Sound Chinook salmon stocks cannot be identified with certainty because of the inability to assess total production of natural stocks in Puget Sound, coupled with the changes in fishery patterns and hatchery production over the 1975 to 2019 time period. Data limitations notwithstanding, it is still possible to make some generalizations about the current status of Puget Sound escapement indicators based on the recent past at both the aggregate and individual population levels. Spring Chinook salmon in the Nooksack and Skagit rivers, for example, exhibit annual variability with no apparent escapement trend. Since ESA listing in 1999, aggregated summer/fall escapements have averaged around 25,200 with no apparent trend, however, they have varied considerably, peaking at approximately 45,000 in 2004 then declining to a low of around 10,300 in 2011. Some variation on this general theme emerges at the individual stock level (Section 2.3.4). The average summer/fall escapement in 2009-2020 was about 17\% lower than the long-term average during 1999-2020 with exception of Lake Washington, which remained nearly the same (Appendix Table B7). Although it is important to acknowledge the influence of the time period choice on conclusions about recent abundance trends (i.e., near-record escapements were seen for many Puget Sound populations in the early 2000s), the observation of low escapements in recent years for multiple populations suggests this group of stocks remains depressed overall. Future assessments of escapement trends should attempt to separate hatchery strays from natural-origin spawners, where data permit.

### 3.2.4.2 Coastal Washington

Coastal Washington is the only region in Washington accessible to anadromous salmonids where Chinook salmon are not listed under the U.S. Endangered Species Act. Consequently, salmon fishery management of the coastal Chinook salmon stocks in this region has one less regulatory framework to consider, but still has to balance conservation needs with state and
tribal co-management, federal fishery management plans, and international agreement under the PST. Additionally, compared to Puget Sound, the confounding influence of hatchery production on trend assessments is considerably less.

The aggregate escapement of spring and summer Chinook salmon CTC escapement indicator stocks in the Quillayute, Hoh, and Queets rivers and Grays Harbor ranged from a high of 11,700 in 1989 to a low of 2,300 in 2007 (Figure 3.31). The Hoh River spring/summer Chinook population has met its PSC escapement goal in eight out of 17 years since it was accepted by the CTC in 2004. Over the same period, the Queets River spring/summer population has only met its PSC escapement goal three times, although two of those were in recent years (2016, 2017). Terminal harvest rates on these stocks have averaged $10 \%$ since the 1999 PST Agreement went into effect and were $4 \%$ in 2019. There is no CTC exploitation rate indicator stock that is considered representative of this stock group. However, spring and summer Chinook with CWTs were intermittently released from Sol Duc Salmon Hatchery in the Quillayute Basin through the mid-1990s and discontinued for about 10 years before starting a new summer Chinook tagging program with the 2004 brood. Based on limited information from these tag recoveries that generally showed poor survival, the Quillayute summer stock has a northerly ocean catch distribution. Exploitation rates cannot be determined because recoveries are low and escapement area sampling appears inadequate in some years to appropriately index exploitation rates.

Figure 3.31-Escapements, terminal harvests, and terminal harvest rates for the aggregate of Washington coastal spring/summer Chinook salmon PSC escapement indicator stocks.

Note: Terminal harvest not available for last year.

Coastal Washington fall Chinook salmon escapement indicator stocks include Quillayute, Hoh, Queets, and Grays Harbor, which have PSC-accepted escapement goals, along with the Hoko stock that does not have a PSC escapement goal. The coastal fall Chinook salmon aggregate escapement has ranged from a low of 13,800 in 1983 to a high of 57,600 in 1988 (Figure 3.32).

Similar to the Washington Coast spring/summer stocks, Washington coastal fall stocks are characterized by escapement declines since the highs of the late 1980s, and generally stable escapements in recent years (Section 2.3.4.2). Over the entire 1980 to 2019 time period, terminal harvest rates have varied substantially without a definitive trend and have averaged about $30 \%$ since 1999. With the exception of the Hoko where there are no terminal fisheries, harvest in terminal fisheries is a mixture of directed catch on Chinook salmon stocks and incidental catch while targeting other species (Figure 3.32).

Figure 3.32-Escapement, terminal harvest, and terminal harvest rates for the aggregate of Washington coastal fall Chinook salmon PSC escapement indicator stocks.

Note: Terminal harvest not available the last year.

Fall Chinook salmon hatchery production is limited on the Washington Coast compared to Puget Sound, and not extensive in the CTC indicator stock basins. The current fall Chinook salmon hatchery programs include the Hoko Falls Hatchery that releases smolts for natural stock supplementation/CWT indicator stock purposes, Salmon River Fish Culture Hatchery in the Queets Basin, and Humptulips Salmon Hatchery in the Grays Harbor watershed. Other significant programs outside of the CTC escapement indicator stock programs include releases from Makah National Fish Hatchery on Tsoo-Yess River (formerly Sooes River), and Forks Creek Hatchery in Willapa Bay. All of these hatchery programs influence the management of terminal fisheries and the extent of directed harvest on fall run Chinook salmon of Washington Coast origin.
Despite a lack of clear trends in escapement for coastal Chinook salmon stocks (Section 2.3.4.2), conclusions on stock status and population trends are speculative without a full CWT-based run reconstruction that can account for total production. Ocean fishery impacts for these stocks, however, are estimated using the Queets CWT indicator tag releases under the assumption that it is a suitable surrogate for the exploitation and ocean distribution of other fall Chinook stocks on the Washington Coast. From a simple fishery distribution basis, the portion of the Queets
exploitation rate indicator stock impacted in ocean fisheries shows no apparent temporal trend and has averaged about $40 \%$ of the total accounting in all fisheries and escapements since the mid-1980s (CTC 2021), while terminal returns have declined over the same period. Further investigation and analysis are needed to confirm whether the Queets indicator stock truly is a suitable surrogate for other Washington Coast fall Chinook salmon stocks; however, the data available to conduct such an analysis are limited.

Queets CWT indicator tag releases were used to produce plots for a synoptic evaluation of the four coastal Washington fall Chinook salmon stocks with PSC escapement goals—Quillayute, Hoh, and Queets rivers, and Grays Harbor. Queets CWT indicator stock releases were assumed to be representative of the exploitation and ocean distribution of Quillayute, Hoh, Queets, and Grays Harbor natural stocks. All four stocks have active terminal fisheries with harvest rates that can vary considerably from year to year.

A simultaneous evaluation of spawning escapements and assumed cumulative MRE exploitation rates shows management of Queets River fall Chinook salmon (Figure 3.33) in the safe zone in all but four years, with exploitation rates below $U_{\text {MSy }}$ and spawning escapement exceeding SmSY. Escapements in 2002 were in the buffer zone, while those in 1999, 2007, and 2018 were below $0.85 * S_{\text {MSY, }}$ putting them in the "Low Escapement Low Exploitation" zone. Management for escapement and MRE exploitation rate was in the safe zone in all years for Quillayute (Figure 3.34) and Hoh (Figure 3.35) rivers, with the exception of Quillayute in 2014, where escapement was in the buffer zone. As evidenced by the high $U_{\text {MSY }}$ values ( 0.87 for Queets and Quillayute; 0.90 for Hoh), productivity of these stocks is assumed to be high and suggests less stringent management than is required for stocks with lower U $\mathrm{U}_{\text {msr }}$. This assumption is supported by historical stock-recruit analyses that were conducted in the mid1980's; however, given their age, it is a worthwhile exercise to re-examine these relationships. For Grays Harbor Chinook (Figure 3.36), the current escapement goal was accepted by the CTC in 2014. In the years since then with available data, two were in the safe zone, one was in the buffer zone, one was in the "Low Escapement Low Exploitation" zone, and three were in the "High Escapement High Exploitation" zone. No years have fallen into the high risk category since the escapement goal was accepted in 2014. From this synoptic evaluation perspective, these coastal Washington stocks exhibit a track record of sustainable management. Further, this view of the fishery impact and escapement data suggests that much of the variation in escapements for these stocks has been driven by non-fishing factors (e.g., anomalously high or low marine survival).

Figure 3.36-Grays Harbor fall Chinook salmon spawning escapement and cumulative maturerun equivalent exploitation rate calculated from Queets River PSC indicator CWTs.

### 3.2.4.3 Columbia River

### 3.2.4.3.1 Columbia River Summers

Mid-Columbia Summer Chinook includes populations in the Okanogan, Methow, Entiat, and Wenatchee rivers as well as hatchery production from Wells and Chief Joseph hatcheries. Since 2019, mid-Columbia Summer Chinook have been managed for an interim management goal of 29,000 hatchery and natural origin adults at the Columbia River mouth. The management goal is based on an interim combined spawning escapement goal of 20,000 hatchery and natural adults.

The synoptic evaluation (Figure 3.37) shows Rock Island Dam counts as escapement for this stock group. Except for 2018, these counts have exceeded 40,000 since 2009, while the stock experienced MRE exploitation rates below UMSY. The CTC goal of 12,143 adult Chinook salmon past Rock Island Dam was developed prior to sport and non-treaty tribal fisheries that now take place above Rock Island Dam, so the dam counts are consistent with the goal but overestimate escapement. Except for 2015, Colville tribal catches above Rock Island Dam have been under 3,600 and sport catches above Priest Rapids Dam since 2009 have been between 2,500-4,000, so escapement was still well above goal. The synoptic evaluation shows the Columbia Summer stock group in the safe zone in all but two years since 1998 (Figure 3.37). Until the recent 2016 brood, mid-Columbia Summers demonstrated positive survival deviations since 1995, within less than 1.5 standard deviations (Figure 3.38).

Figure 3.37-Columbia River Summer Chinook salmon spawning escapement past Rock Island Dam and cumulative mature-run equivalent exploitation rate calculated from Wells Hatchery PSC indicator CWTs.

Figure 3.38-Marine survival index (standardized to a mean of zero) for Columbia River Summer Chinook salmon.

### 3.2.4.3.2 Columbia River Fall

The Columbia River Fall stock group has two escapement indicator stocks: Upriver Brights and Lewis River Wilds. In the U.S. v. Oregon Management Agreement, the Upriver Bright Fall Chinook management unit is comprised of all bright fall Chinook populations returning above Bonneville Dam, including those in the Deschutes, upper Columbia and Snake rivers, but the Upriver Bright escapement indicator only represents fall Chinook in the Columbia River above McNary Dam.

From 2009-2019, MRE exploitation rates for Upriver Brights were usually 40-50\%, while escapements exceeded $\mathrm{S}_{\text {MSY }}$ (Figure 3.39). The three most recent broods for Columbia River falls have had worse survival than the 2007-2013 broods (Figure 3.40 and Figure 3.41), and the MRE exploitation rate was reduced.

For Lewis River Wild fall Chinook salmon, exploitation rates since 2008 have been well below the estimated $U_{\text {MSY }}$ of $76 \%$ and the PSC-agreed escapement goal has been above $85 \%$ of $\mathrm{S}_{\text {MSY }}$ (Figure 3.42). Recent broods of Lewis River wild fall Chinook have had better survival than previous broods since 2008 (Figure 3.43).

### 3.2.4.4 Coastal Oregon

### 3.2.4.4.1 North Oregon Coast

Total estimated spawning escapement for the NOC aggregate stock has ranged from approximately 24,000 Chinook salmon in 2008 to 137,000 in 1988. The recent 11-year (20102020) average for aggregate escapement is approximately 70,500 . Estimated escapement in 2020 was 76,901 . The abundance forecast expressed in terms of spawning escapement is approximately 68,000 for 2021.

After low escapements from 2007 to 2009, the NOC stock aggregate had returned to average or above-average escapement from 2013 onwards through 2016. All three NOC escapement indicator stocks-the Nehalem, Siuslaw, and Siletz-failed to achieve their escapement objectives in 2007 and 2008. The Nehalem stock did not attain its goal in 2009 and 2010. The most recent year's escapement for the NOC showed improved results, with all three escapement indicators exceeding their escapement goals. It is likely that the NOC has recently experienced a period of lower-than-normal marine survival, as indicated in Figure 3.44. The later years in the survival index are generated from incomplete broods, and although it is tempting to interpret these initial signals in both fisheries recruitment and robust escapement, these results are only preliminary.

Management actions in terminal fisheries, along with reductions in AABM fisheries, and better-than-average survival rates (Figure 3.44) appear to have contributed to the increased escapements following a period of decline in the 2007-2009 return years. More conservative terminal fishery management undoubtedly contributed towards the escapement performance above goal for the Siuslaw and likely the Siletz stocks for return year 2020. This terminal fisheries action, paired with forgone fishing opportunity in both AABM and ISBM fisheries during the 2020 catch year due to COVID-19 related travel restrictions undoubtedly contributed to several stocks within the NOC aggregate outperforming escapement return expectation.

Figure 3.44-Marine survival index (standardized to a mean of zero) for the Salmon River hatchery stock of Chinook salmon.

Note: Brood years 1976-2016 are shown, with the exception of 1981, for which there is no information.
A review of the synoptic plots shows that three NOC escapement indicator stocks have spent most years in the upper left sector (high escapement, low exploitation). Exploitation rates have been lower and escapements have been higher than required for MSY for the majority of years for each stock. Of the three stocks, the Nehalem stock has spent more years below the escapement objective than the others, and the Siuslaw stock has the most years with high exploitation rates.

The Nehalem River stock of Chinook salmon has experienced a wide array of both exploitation and escapement from 1979 to 2018 From 2006 to 2010 this stock failed to meet $85 \%$ of its escapement goal (Figure 3.45). In 2017 and 2018, the Nehalem missed goal but was above 85\% of the escapement goal.

The Siletz River stock of Chinook salmon exhibits high productivity as demonstrated by one of the higher $U_{\text {MSYS }}$ presented in this chapter. All but one of the observed points of escapement and exploitation are within the safe zone (Figure 3.46). Recent year's escapements (2010-2018) have increased over lower escapements observed in return years 2007 to 2009. While meeting goal in the last year of the examined series (2018), the poor survival index for the aggregate noted earlier coupled with high exploitation rates should indicate caution for this stock's overall performance into the near future.

The Siuslaw stock of Chinook salmon, similar to the Nehalem stock, has experienced a wide range of both escapement and exploitation since 1979 (Figure 3.47). Most of the observations of escapement below $S_{\text {MSY }}$ occurred during the pre-Treaty period of 1979 to 1984. Recently, this stock has failed to perform to escapement goal for three years prior to the most recent escapement year in 2020. Indications from these poor escapement performances, high exploitation and low survival are flags to cautious management into the near future not only for the Siuslaw stock but for the aggregate as a whole.

Figure 3.47-Mature-run equivalent exploitation rate, spawning escapement, and threshold reference lines for exploitation rate and spawning escapement by CY for the Siuslaw River stock of Chinook salmon, 1979-2018.

### 3.2.4.4.2 Mid-Oregon Coast

After a period of declines in escapement from 2005 to 2008, the Mid-Oregon Coast (MOC) stock aggregate rebounded to historical averages during the 2010-2016 return years. Total aggregated estimated escapement for the MOC has ranged from a low of 14,646 in 2009 to a high of 110,000 in 2015. The 10-year average (2011-2020) escapement for the MOC is about 41,000 . Estimated escapement for the MOC stock group in 2020 was about 27,000 . Forecasted escapement for the 2021 return year is at about 26,000 spawning adults. Previous year's recent marine survival brood year metrics showed below average survival and translated into reduced expectations for this aggregate's production. The most recent indication is that marine survival is still on the downswing for this aggregate (Figure 3.48), so there is reason for tempered expectations for the coming year's terminal return in 2021.

Figure 3.48-Marine survival index (standardized to a mean of zero) for the Elk River hatchery stock of Chinook salmon.

Note: troll (Areas 1-5) and tidal sport (Areas 1, 2E, 2W) are the components of the NBC AABM fishery.
${ }^{1}$ Since 1998, the catch accounting year for troll fisheries was set from October 1 to September 30. To make comparisons to previous years more meaningful, the same catch accounting period was applied for years prior to 1998.
${ }^{2}$ Troll catches from 1996 to 2004 have been updated with data from DFO (2009).

${ }^{1}$ Net catches from 1996-2004 have been updated with data from the Catch Finalization Project
${ }^{2}$ Prior to 1992, catch was not reported as 'inside' or 'outside'. Therefore 'inside' catch for those years represents total tidal sport catch.
${ }^{3}$ First Nations catch is mainly commercial catch 1996-2004 has been updated.

Note: NA = Not available.
${ }^{1}$ The historical time series of catches in this year's report has changed from previous year's report. Catches after 1980 have been broken out into non-Treaty net and Treaty Indian due to the inability to separate Treaty Indian commercial versus noncommercial. Non-treaty net includes catches by Wanapum and Colville tribes. Sport and total catches from 1975 to 1980 are consistent with previous year's reports.
${ }^{2}$ The Treaty Indian Net catch estimates for 1975-1979 are not available, but are believed to be of the magnitude seen after 1979; the catch for 1979 represents spring-run catches and does not include catch estimates for summer and fall stocks. Sport and total catch estimates from 1975-1979 are consistent with previous year's reports, but the total is underestimated because of the missing estimates.
${ }^{3}$ Preliminary.

Table A22.-Oregon ISBM Chinook salmon landed catch (LC), releases (Rel.), and incidental mortality (IM).

Catch years 1975-2018 include only NOC aggregate catch. Catch years 2019 and onwards are the product of both NOC and MOC aggregated catch.

All LC from 1975 to 1984 were taken prior to implementation of the PST.
${ }^{2}$ LC in AABM fisheries from 1985 to 1994 were taken under fixed ceiling management per the 1985 PST Agreement. Catches from 1995 to 1998 were between agreements. LC
from 1999 to present was taken commensurate with abundance-based management per the 1999 PST Agreement (1999-2008) and the 2009 PST Agreement (2009-present).
${ }^{3}$ Southeast Alaska non-Treaty catches are primarily Alaska hatchery add-ons, but include terminal exclusions in some years from terminal catches from the Situk, Taku and Stikine rivers.
${ }^{4}$ US and Canadian ISBM fisheries had a pass-through obligation from 1985 to 1994 under the 1985 PST Agreement and have operated with ISBM index obligations since 1999, under the 1999 and 2009 Agreements
${ }^{5}$ Catches in the Canada ISBM column include catches in the Strait of Georgia (troll and sport), Central British Columbia troll, and Northern British Columbia net and mainland sport
fisheries from 1985 to 1994 when these were AABM fisheries operating under fixed ceiling management provisions of the 1985 PST Agreement.
${ }^{6}$ Does not include SEAK AABM fishery non-Treaty catch from hatchery add-on and terminal exclusion.

Note: LIM = Legal Incident Mortality, SIM = Sublegal Incident Mortality.
${ }^{1}$ The IM estimates presented in this table are not equivalent to LC on a one-to-one fish basis because of the inclusion of SIMs, which are smaller, less mature fish.
${ }^{2}$ IM estimates (LIM + SIM) are available for AABM fisheries from 1985 to present (CTC 2011).
${ }^{3}$ The PST total needs to be viewed with caution per footnote 1.
${ }^{4}$ Does not include SEAK AABM fishery non-Treaty catch from hatchery add-on and terminal exclusion.

Note: NA = Not available.
${ }^{1}$ GW refers to Gitwinksihlkw, the location of the lower fish wheels on the Nass River used to capture Chinook salmon for the MR estimate.
${ }^{2}$ Estimates prior to 1990 are visual counts, 1990-2000 and 2004-2008 are based on time series calibration, 2001-2003 and 2009-2020 are maximum likelihood estimates based on MR estimates.
Genetic Stock Identification.
${ }^{4}$ Large wild Atnarko Chinook salmon.

${ }^{1}$ Escapement was estimated by MR methods from 1983 to 1985,2000 to 2002, and 2004 to 2012 . All other years are calibrated values that have been estimated using a
relationship between $M R$ and peak methods.
${ }^{2}$ Escapement was estimated by MR methods from 1995 to 2020. All other years were calibrated values that have been estimated using a relationship between MR and peak methods.
${ }^{3}$ Escapement was estimated by electronic counts in 2008, 2009, 2012, 2020. All other years were calibrated values that have been estimated using a relationship between electronic counts and peak methods.
Escapement was estimated by MR methods from 2010 to 2018 and in 2020. All other years were calibrated values that have been estimated using a relationship between MR and peak methods.

${ }^{1}$ Escapement estimated from MR studies conducted with Treaty-related funding. For the Stillaguamish River, 1988-2007 estimates are converted to a tGMR equivalent using a regression relationship derived from ground based and tGMR escapements from the period 2008 to 2016 when both methods were used concurrently
${ }^{2}$ Estimate of total natural spawners (hatchery + natural) during the spring Chinook salmon escapement accounting period (prior to Oct. 1); includes some early-timed summer/fall Chinook salmon in the south Fork but is assumedly spring Chinook salmon only in the north fork/middle fork Chinook salmon (due to spawn timing differences).
${ }^{3}$ Natural-origin (NOR) spring Chinook salmon isolated from total natural spawners based on carcass mark-sampling details (otolith thermal marks, fin clips, CWTs) and genetic stock identification.
${ }^{4}$ Escapement excludes brood stock collected for supplementation program. Total run includes redd count based escapement of all natural spawners, terminal catch, and adult brood stock collected for supplementation and PSC indicator program.

${ }^{1}$ Based on a spawner-recruit relationship analysis of model data which included both hatchery and wild fish, an interim goal of 12,143 adult Mid-Columbia Summers at Rock Island Dam was developed. For consistency with the goal, the escapement time series reported here is total adult Rock Island Dam count. The terminal run is that reported for Upriver Summer Chinook in the Joint Staffs Reports as the Bonneville Dam Count plus catch in lower river fisheries.
${ }^{2}$ This is the number of naturally spawning adult fish in the Lewis River. The terminal run given is the escapement plus the Lewis River sport catch of wild adults.
${ }^{3}$ Estimate is based on the ratio of redds above and below Sherar's Falls. The time series of data through 2009 were updated based on a comprehensive analysis done by Warm Springs, ODFW and CRITFC staff (Sharma et. al. 2010). Deschutes fall Chinook are part of the Upriver Bright management unit, but are not listed in Attachment I.
 given are McNary adult dam count minus adult sport and broodstock above the dam. The terminal run is the Columbia River mouth terminal run of Upriver Brights minus the Deschute River fall chinook terminal run.

Table B10.-North Oregon Coastal escapements as estimated via traditional habitat expansion methods and terminal runs (t. run) of Pacific Salmon Commission Chinook Technical Committee wild Chinook salmon escapement indicator stocks.

Note: Estimates presented in boldface represent estimates generated from direct MR studies.
Note: NA = Not available.

[^0]:    Note: The Keta, Blossom, and King Salmon rivers and Andrews Creek stocks were dropped as escapement indicator stocks in 2013 and Grays Harbor fall was added in 2014. In 2019, the Deschutes and Chickamin rivers stocks were dropped and the Atnarko, Lower Shuswap. Skagit spring, and Skagit summer/fall stocks were added bringing the total number of current indicator stocks with PSC-agreed escapement goals to 24.

[^1]:    ${ }^{1}$ Escapement goals reviewed by the CTC are based on analyses that follow the guidelines developed in CTC (1999).

[^2]:    ${ }^{2}$ Scott A. McPherson, ADF\&G, to Keith Weiland, ADF\&G. 1991 memorandum. Available from ADF\&G, Douglas Island Center Building, $8023^{\text {rd }}$ Street, P. O. Box 240020, Douglas, AK 99824-0020.
