|  |  | WDFW | Washington Department of Fisheries and Wildlife |

## EXECUTIVE SUMMARY

This report contains the results of the Chinook Technical Committee (CTC) annual exploitation rate assessment and the final preseason Chinook model calibration for 2005 (CLB 0506). Results include the Abundance Indices (AIs) for the Aggregate Abundance Based Management (AABM) fisheries and Individual Stock Based Management (ISBM) Indices for each party (country) and a summary of preseason forecast methods by stock.

## AABM Abundance Indices and Associated Catches

The AIs for the three AABM fisheries, i.e., Southeast Alaska All Gear (SEAK), Northern British Columbia Troll and Queen Charlotte Islands Sport (NBC), and West Coast Vancouver Island Troll and Outside Sport (WCVI), are presented in Table 1. The 1999 Agreement specified that the AABM fisheries were to be managed through the use of the AIs. Preseason AIs are used to set allowable catch limits for management in the upcoming fishing season. Subsequently, postseason AIs (from the following year's calibration) are used to track overage and underage provisions. Each calibration provides the first postseason AIs for the previous year and the preseason AIs for the current year. The first 2004 postseason AIs and the 2005 preseason AIs have now been finalized.

Table 1. Abundance Indices for 1999 to 2005 for the SEAK, NBC, and WCVI AABM fisheries.

|  | SEAK |  | NBC |  | WCVI |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Preseason | Postseason | Preseason | Postseason | Preseason | Postseason |
| 1999 | 1.15 | 1.12 | 1.12 | 0.97 | 0.60 | 0.50 |
| 2000 | 1.14 | 1.10 | 1.00 | 0.95 | 0.54 | 0.47 |
| 2001 | 1.14 | 1.29 | 1.02 | 1.22 | 0.66 | 0.68 |
| 2002 | 1.74 | 1.82 | 1.45 | 1.63 | 0.95 | 0.92 |
| 2003 | 1.79 | 2.17 | 1.48 | 1.90 | 0.85 | 1.10 |
| 2004 | 1.88 | 2.06 | 1.67 | 1.83 | 0.90 | 0.98 |
| 2005 | 2.05 |  | 1.69 |  | 0.88 |  |

In general, the AIs for 1999 through 2001 are low compared to AIs in the late 1980s and early 1990s but values have increased since 2002. The recent AI values are comparable to the higher values in the time series. The Agreement specifies an allowable catch for each AI for each fishery. The specified Treaty catch by fishery and year and the actual (observed) catches are shown in Table 2.

Table 2. Observed catches and postseason allowable catches for 1999 to 2004, and preseason allowable catches for 1999 to 2005, for AABM fisheries.

| Year | Pacific Salmon Treaty Allowable and Observed Catches |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | SEAK |  |  | NBC |  |  | WCVI |  |  |
|  | Preseasor <br> tllowabl Catch | Postseason <br> Allowable Catch | Observed Catch | Preseason <br> Allowable Catch | Postseason <br> Allowable Catch | Observed <br> Catch | Preseason <br> Allowable Catch | Postseason <br> Allowable Catch | Observed Catch |
| 1999 | 192,800 | 184,200 | 198,842 | 145,600 | 126,100 | 86,726 | 128,300 | 107,000 | 36,413 |
| 2000 | 189,900 | 178,500 | 186,493 | 130,000 | 123,500 | 31,900 | 115,500 | 86,200 | 101,438 |
| 2001 | 189,900 | 250,300 | 186,919 | 132,600 | 158,900 | 43,500 | 141,200 | 145,500 | 117,670 |
| 2002 | 356,500 | 371,900 | 357,133 | 192,700 | 237,800 | 150,137 | 203,200 | 196,800 | 165,036 |
| 2003 | 366,100 | 439,600 | 380,152 | 197,100 | 277,200 | 191,657 | 181,800 | 268,900 | 175,821 |
| 2004 | 383,500 | 418,300 | $\begin{array}{r} 428,773^{1} \\ 433,446 \\ \hline \end{array}$ | 243,600 | 267,000 | 241,508 | 192,500 | 209,600 | 216,166 |
| 2005 | 416,400 | - | - | 246,600 | - |  | 188,200 | - | - |

${ }^{1}$ The lower value results from subtracting a terminal exclusion catch for the Stikine River in 2004, which is in dispute.

The Agreement specifies that overage/underage provisions apply to both AABM and ISBM fisheries. However, the CTC identified, in a February 12, 2002 letter to the PSC, major technical obstacles and policy concerns for adjusting harvest levels in response to overages and underages. The major problem identified for AABM fisheries is the confounding of forecast and management error in assessing overages and underages. Forecast error is associated with the accuracy of the preseason Abundance Indices (Table 1) which in turn is used to determine the preseason estimate of allowable catch. Management error is related to the harvest manager's ability to attain the preseason estimates of allowable catch. Harvest managers have no prior knowledge of the postseason estimate of allowable catch, which can be quite different from the preseason estimate (Table 2).

Until an approach for full implementation has been developed and accepted by the PSC, the Commissioners have instructed the CTC to track overages and underages relative to agreed-upon harvest objectives. Table 3 shows the difference between the postseason allowable catch and the observed catch in AABM fisheries for 1999-2004, and the cumulative differential for those years. All three AABM fisheries have cumulative underages. In SEAK, observed catches have been below final allowable catches for three of the six years; the cumulative differential is $-5.7 \%$ or $-5.4 \%$, depending on how the terminal exclusion for the Stikine River in 2004 is treated. In NBC, observed catches have been below the final allowable catches in all six years; the cumulative differential is $-37.4 \%$. In WCVI, observed catches have been below allowable catches in four of the six years; the cumulative differential is $-19.9 \%$.

Table 3. Differences between observed Treaty catch and the postseason Treaty allowances as number of fish and percentages of allowable catch for AABM fisheries in 1999 to 2004.

| Year | SEAK |  | NBC |  | WCVI |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number of Fish | Percent Difference | Number of Fish | Percent Difference | Number of Fish | Percent Difference |
| 1999 | +14,642 | +7.9\% | -39,374 | -31.2\% | -70,587 | -66.0\% |
| 2000 | +7,993 | +4.5\% | -91,600 | -74.2\% | +15,238 | +17.7\% |
| 2001 | -63,381 | -25.3\% | -115,400 | -72.6\% | -27,830 | -19.1\% |
| 2002 | -14,767 | -4.0\% | -87,663 | -36.9\% | -31,764 | -16.1\% |
| 2003 | -59,448 | -13.5\% | -85,543 | -30.9\% | -93,079 | -34.6\% |
| 2004 | $\begin{aligned} & +10,473 \\ & +15,146 \end{aligned}$ | $\begin{aligned} & +2.5 \% \\ & +3.6 \% \end{aligned}$ | -25,492 | -9.5\% | +6,566 | +3.1\% |
| Cum. | $\begin{aligned} & -104,488 \\ & -99,815^{1} \end{aligned}$ | $\begin{aligned} & -5.7 \% \\ & -5.4 \% \end{aligned}$ | -445,072 | -37.4\% | -201,456 | -19.9\% |

${ }^{1}$ The lower value results from subtracting a terminal exclusion catch for the Stikine River in 2004, which is in dispute.

## ISBM Indices

For ISBM fisheries, the Agreement specified that Canada and the United States would reduce base period exploitation rates on specified stocks by $36.5 \%$ and $40 \%$, equivalent to ISBM indices of $63.5 \%$ and $60 \%$ percent, respectively. This requirement is referred to as the 'general obligation' and does not apply to stock groups that achieve their CTC agreed escapement goals. Estimated ISBM fishery indices are shown in Table 4 for Canadian fisheries and Table 5 for United States (U.S.) fisheries. Both tables present coded-wire tag (CWT)-based indices for 2003, and Chinook model-based indices for 2005. The agreement specifies that the ISBM indices be forecasted preseason and evaluated postseason for each escapement indicator stock listed in Attachments I to V of the Chinook Chapter.

## CWT-based Indices in 2003

All Canadian ISBM indices from the CWT-based estimates for 2003 show that exploitation rates were reduced more than required under the agreement for all stocks or stock groups for which the indices could be calculated. Two of the 15 U.S. ISBM indices for the CWT-based estimates for 2003 were reduced more than required under the agreement. Of the 13 U.S. CWT-based ISBM indices that exceeded 0.60 , ten (Upriver Brights, Quillayute, Queets, Hoh, Lewis, Harrison, Mid-Columbia Summers, Nehalem, Siletz, and Siuslaw) have agreed escapement goals and all ten exceeded their goals in 2003.

## Predicted ISBM Indices for 2005

Seven of the 19 ISBM indices for Canada in 2005 based on outputs from calibration 0506 are above the allowable value of 0.635 for Canadian ISBM fisheries. Of the seven, only far north migrating Oregon Coast and Upriver Brights have CTC agreed escapement goals. Ten of the 24 U.S. ISBM indices for 2004 based on calibration 0506 are above the allowable limit of 0.60 for U.S. ISBM fisheries. Nine of the 10 have CTC agreed escapement goals: Queets, Hoh, Quillayute, Upriver Brights, Lewis, Harrison, Nehalem, Siletz, and Siuslaw.

Table 4. Canadian 2003 ISBM indices based on CWT and the 2005 indices predicted from the PSC Chinook Model.

|  |  | Canadian ISBM Indices |  |
| :---: | :---: | :---: | :---: |

| Far North Migrating OR Coastal Falls ${ }^{3}$ | Nehalem ${ }^{2}$, Siletz ${ }^{2}$, Siuslaw ${ }^{2}$ | NA | 0.674 |

${ }^{1}$ Not available (NA) because of insufficient data (lack of stock specific tag codes, base period CWT recoveries, etc).
${ }^{2}$ Stock or stock group with a CTC agreed escapement goal.
${ }^{3}$ Stock group listed in Annex 4, Chapter 3, Attachment V.
${ }^{4}$ An inconsistency was discovered between the approaches used to calculate the model-based and CWT-based indices. The former included harvest rates for terminal sport while the latter did not. Terminal sport harvest rates are now included in the calculation of both indices. Further review is yet required to determine whether the base period terminal sport harvest rates obtained from analyses of Big Qualicum CWT recoveries adequately represent impacts that would have occurred on Cowichan Chinook.
${ }^{5}$ Several problems have been identified in the approach previously used to calculate the CWT-based indices for Nanaimo Chinook. Until these problems are resolved, indices for this stock will not be reported.
${ }^{6}$ Although model-based indices were previously calculated separately for Cowichan and Nanaimo, these did not adequately represent impacts on either LGS stock because the model-based data represent an aggregate of the two stocks and methods do not currently exist to correctly disaggregate these data for calculation of the ISBM values. Until such methods are developed, a single index value only will be reported representing the aggregate.
${ }^{7}$ The terminal sport harvest rates for Chilliwack Hatchery Chinook, the indicator stock, were removed from the calculation for the Harrison River naturals because sport harvest has been essentially zero on the natural population.
${ }^{8}$ An inconsistency was discovered between the approaches used to calculate the model-based and CWT-based indices. The former included harvest rates for terminal sport while the latter did not. Terminal sport harvest rates are now included in the calculation of both indices. A more extended review of the indices for WCVI Chinook will be carried out to determine whether they adequately represent impacts on the WCVI wild aggregate.
${ }^{9}$ For Canadian ISBM fisheries, Lake Washington and Green the same distribution and Index value are assumed.

Table 5. U.S. 2003 ISBM indices based on CWT and the 2005 indices predicted from the PSC Chinook Model. Order of the stock groups corresponds to Annex 4, Chapter 3, Attachment V of the PST 1999 Revised Annexes.

|  |  | U.S. ISBM Indices |  |
| :---: | :---: | :---: | :---: |
| Stock Group | Escapement Indicator Stock | CWT Indices for 2003 | Model Indices for 2005 |
| Washington Coastal Fall Naturals | Hoko | NA ${ }^{1}$ | 0.444 |

${ }^{1}$ Not available (NA) because of insufficient data (lack of stock specific tag codes, base period CWT recoveries, etc).
${ }^{2} \mathrm{NC}$ means that the current model assumes the stock is not caught in U.S. ISBM fisheries.
${ }^{3}$ Stock group listed in Annex 4, Chapter 3, Attachment IV.
${ }^{4}$ Stock with a CTC agreed escapement goal.

## Stock Forecasts

In general, the model does a very good job of matching the agency-supplied forecasts (average error $=-0.7 \%$, standard deviation $=13 \%$, median error $=-0.9 \%$ ). Agency forecasts are, on average, also good predictors of observed returns (average error $=-10 \%$, standard deviation $=$ $40 \%$, median error $=-11 \%$ ). The model's prediction of observed returns, including stocks for which there are agency forecasts, is also good (average error $=-6 \%$, standard deviation $=36 \%$, median error $=-9 \%$ ).

## 1. INTRODUCTION

The annexes of the Pacific Salmon Treaty (PST), dated June 30, 1999, changed the way Chinook salmon fisheries were managed by the Pacific Salmon Commission (PSC). Fisheries are no longer designated as "ceiling" or "pass through," but as Aggregate Abundance Based Management (AABM) or Individual Stock Based Management (ISBM) fisheries. AABM fisheries are managed according to the abundance of Chinook salmon in each fishery. ISBM fisheries are managed to control impacts on individual stocks. Preseason allowable catch in each AABM fishery (Southeast Alaska All Gear (SEAK), Northern British Columbia Troll and Sport (NBC), and West Coast Vancouver Island Troll and Outside Sport (WCVI) is determined through an Abundance Index (AI) calculated from an agreed preseason calibration of the Chinook Technical Committee (CTC) Chinook model (see Table 1 of Chapter 3 in the Agreement). This same calibration is also used to compute the postseason AIs for the previous year. Under the Agreement, annual aggregate impacts in Canadian and U.S. ISBM fisheries on specified stocks or stock groups are to be reduced by $36.5 \%$ and $40.0 \%$, respectively, from the average of those in the base period (1979-1982). Such reductions will remain in effect until these fisheries can be managed to achieve escapement at maximum sustained yield (MSY) or some other CTC agreed to biologically based escapement goal. Preseason and postseason indices are also calculated for ISBM fisheries using the Chinook model.

This annual report describes the methods and results of: 1) the cohort analysis used to estimate exploitation rates from coded-wire tag (CWT) data, and 2) the PSC Chinook model calibration. The results of the 2005 preseason calibration (CLB 0506) are based on completion of the CWT exploitation rate analysis for indicator stocks through 2003 fisheries, coast-wide data on catch, spawning escapements and age structure through 2004, and forecasts of Chinook returns expected in 2005. This report includes:

1) estimates of the abundance indices for the years 1979 through 2004 and a projection for 2005 for the AABM fisheries,
2) estimates of the non-ceiling indices, referred to as the ISBM indices in this report, for 1999 to 2003 and projections for the 2005 ISBM fisheries,
3) estimates for 1979 through 2004 and a projection for 2005 of stock composition in the AABM and other fisheries,
4) the distribution of landed and total fishing mortality in all fisheries for the indicator stocks,
5) estimates of harvest rates (fishery indices) in the AABM fisheries,
6) forecast methods and results for selected stocks, and
7) survival indices for selected stocks.

Appendices A to L summarizes the indicator stocks, ISBM indices, fisheries, forecasts, survival indices, ocean exploitation rates, distribution of total mortality rates and indices, abundance indices, stock composition of AABM fisheries, abundance indices, fishery indices, exploitation rate indices, and tag codes, respectively.

## 2. METHODS

The exploitation rate assessment is performed through cohort analysis, a procedure that reconstructs the exploitation history of a given stock and brood year using CWT release and recovery data (CTC 1988). The procedure produces a variety of statistics, including total exploitation rates, age and fishery specific exploitation rates, maturation rates, pre-age 2 recruitment survival indices, and annual distribution of fishery-related mortalities. Estimates of age and fishery-specific exploitation and maturation rates from the cohort analysis are combined with data on catches, escapements, non-retention, and enhancement to complete the annual calibration of the CTC Model. The calibration procedure estimates pre-age 2 recruitment survivals for the stocks included in the model.

Results from the annual preseason calibration of the Chinook model are used to calculate: 1) AIs for the three AABM fisheries to determine the allowable 2005 catch of Treaty Chinook; 2) the postseason AIs for the previous year; and 3) preseason and postseason ISBM indices.

Projected AIs for 2005 are used to determine preseason allowable catches for AABM fisheries. The postseason AIs are used to determine postseason allowable catches and to evaluate compliance for AABM fisheries.

For the ISBM fisheries, the Agreement specifies that Canada and the United States will reduce the exploitation rate from the $1979-1982$ base period by $36.5 \%$ and $40.0 \%$, respectively, on stocks that have not achieved their CTC agreed escapement goals. The ISBM index is used to estimate the annual reduction in exploitation rates relative to the base period. Postseason ISBM indices for 2003 are computed using results of the exploitation rate analysis. Forecasts of the 2005 ISBM indices are computed using the CTC model. The Agreement specifies that the ISBM indices estimated through exploitation rate analysis of CWT recoveries will be used for final postseason assessment.

### 2.1. EXPLOITATION RATE ASSESSMENT (THROUGH CALENDAR YEAR 2003)

The exploitation rate (ER) assessment relies on CWT release and recovery data from a set of exploitation rate indicator stocks to estimate: (1) brood year exploitation rates, (2) the distribution of catch and total mortality among fisheries, (3) survival rates to ocean age 2 by brood year; (4) trends in fishery harvest rates, and (5) maturation rates and adult equivalents (AEQs). Statistics reported in the exploitation rate assessment are based on cohort analysis. Cohort analysis simply reconstructs the production of a CWT group by starting with the escapement, catch, and incidental fishing mortality of the oldest age class and working backwards in time to calculate the total abundance of ocean age 2 Chinook salmon, prior to any fishing-related mortality. These re-constructions are based on estimated CWT recoveries by stock, brood year, and age in fisheries and escapements.

The CTC currently monitors 39 exploitation rate indicator stocks with CWTs, but only 36 were used for analyses in this chapter (Table 2.1). An exploitation rate indicator stock is not used in the exploitation rate analysis if the number of CWT recoveries is very limited ${ }^{1}$ or there is no quantitative estimate of tags in the spawning escapement (see footnotes in Table 2.2). Those used

[^0]for exploitation rate analysis and the type of analysis performed for each are shown in Table 2.2. The relationship between the exploitation rate indicator stocks, model stocks, and PST Annex stocks are shown in Appendix A. A list of tag codes used for each exploitation rate indicator stock is provided in Appendix L. Incidental mortality rates used for the 2005 calibration (CLB 0506) are listed in Appendix M. Extrapolation of results to similar stocks and/or generalizations about fishery impacts will only be appropriate to the extent that the exploitation rate indicator stocks are representative of the the stocks groups they are intended to represent in the fisheries.

Table 2.1. The 39 exploitation rate indicator stocks monitored by the CTC, their location, run type, and smolt age. Stocks in bold, italic text were not used in the 2004 exploitation rate analysis.

| Area | Exploitation Rate Indicator Stocks | Location | Run Type | Smolt Age |
| :---: | :---: | :---: | :---: | :---: |

For stocks of hatchery origin and subject to terminal fisheries directed at harvesting surplus hatchery production, ocean
fisheries do not include terminal net fisheries. Otherwise, total fishery includes terminal net fisheries.
${ }_{2}$ Hatchery stock not used to represent naturally spawning stock.
${ }_{4}^{3}$ Only hatchery rack recoveries are included in escapement.
4 Insufficient escapement data for exploitation rate analysis

### 2.1.1. Assumptions of the Analyses

Assumptions used in the cohort analysis and other procedures used in the exploitation rate assessment are summarized below. Detailed discussions of assumptions and parameter values have been reported previously (CTC 1988). The analysis is necessary to calculate the fishery indices for the AABM fisheries and the non-ceiling index for the ISBM fisheries. The primary assumptions of the cohort analysis are:

1) CWT recovery data are obtained in a consistent manner from year to year or can be adjusted to make them comparable. Many of the analyses rely upon indices that are computed as the ratio of a statistic in a particular year to the value associated with a base period. Use of ratios may reduce or eliminate the effect of data biases that are consistent from year to year.
2) For ocean age 2 and older fish, natural mortality varies by age but is constant across years. Natural mortality rates applied by age are: age $2,40 \%$; age $3,30 \%$; age $4,20 \%$; and age 5 and older $10 \%$ (i.e., after fishing mortality and maturation of the age 4 cohort, $10 \%$ of the remaining immature fish die due to natural sources before becoming age 5 fish and before the commencement of fishing the next year).
3) All stocks within a fishery have the same size distribution for each age and the size distribution at age is constant among years.
4) The spatial and temporal catch distribution of sublegal-size fish of a given age from a stock is the same as legal-size fish of a given age of that stock.
5) Incidental mortality rates per encounter are constant between years. The rates vary by fish size (legal or sublegal) and fishery and are those published by the CTC (1997) for troll and sport fisheries. The rates used in CLB 0506 are listed in Appendix M.
6) The procedures for estimating the mortality of CWT fish of legal size during periods of Chinook non-retention (CNR) assume that the stock distribution in any year remains unchanged from the period of legal catch retention in the same year. However, gear and/or area restrictions during CNR fisheries are believed to reduce the number of encounters of legal-size fish. To account for this, the number of legal encounters during the CNR fishery was adjusted by a selectivity factor. A factor of 0.34 was used for the WCVI and Strait of Georgia (GS) troll fisheries. This value was the average selectivity factor calculated from 3 years of observer data in the Alaska troll fishery. A factor of 0.20 was used in the North Central British Columbia (NCBC) troll fishery. This factor corresponds to the proportion of fishing areas that remain open during non-retention periods. A selectivity factor was not required for the SEAK troll fishery since an independent estimate of legal and sublegal encounters has been provided annually.
7) Maturation rates for brood years in which all ages have not matured (incomplete broods) are equal to the average of completed brood years. Maturation rates are stock specific.
8) Recoveries of age 4 (age 5 for spring stocks) and older Chinook in ocean net fisheries are assumed to be mature fish (ocean terminal catches).

In addition, when using the fishery indices as a measure of the change in fishery harvest rates between years, the temporal and spatial distribution of stocks in and among fisheries and years is assumed to be stable.

For AABM fisheries, the fishery indices are presented for both reported catch (same as landed catch) and total mortality; only total mortality indices are presented for the ISBM fisheries. The difference between reported catch and total mortality is incidental mortality, which includes the mortality of legal-size fish in CNR fisheries and the mortality of sublegal-size fish in both retention and CNR fisheries. Management strategies have changed considerably for fisheries of interest to the PSC since 1985. Regulatory changes have included size limit changes, extended periods of CNR in troll fisheries, and mandatory release of Chinook caught in some net fisheries. Estimates of incidental mortality are crucial for assessment of total fishery impacts, yet they cannot be determined directly from CWT recovery data. There are four categories of incidental mortality that are estimated in the Chinook model and the CWT cohort analysis. Legal and sublegal fishery specific mortality rates are applied to the following types of Chinook encounters:

1. Shakers: Chinook below the legal size limit that are encountered, brought to the boat, and released during a Chinook retention fishery.
2. Sublegal CNR: Chinook below the legal size limit that are encountered, brought to the boat, and released during a Chinook non-retention fishery. The mortality rate per encounter applied to sublegal CNR is the same applied to shakers.
3. Legal CNR: Chinook above the legal size limit that are encountered, brought to the boat, and released during a Chinook non-retention fishery.
4. Drop-off: Chinook above or below the legal size limit that are encountered, but are lost from the gear before they reach the boat during either retention or non-retention fisheries. Drop-off mortality is assumed the same for legal and sublegal fish, but can vary by gear type.

There are several methods used to estimate the number of CNR mortalities in the model and the CWT cohort analysis. The 'season length' method uses the relative length of the Chinook retention and non-retention periods. This is usually expressed in days or boat-days. In a related method, direct estimates of CNR encounters provided by the agencies are related to the size of the landed catch. The CWT cohort analysis can also use a method based on catchability coefficients where no associated Chinook retention period exists for the fishery. The 'season length' method used in the exploitation rate assessment was described in CTC (1988). The Chinook model also can use a method, known as the 'RT' method, based on the difference between base period exploitation rates and the current year exploitation rates, and current cohort sizes. In both the season length and RT methods, the stock composition of the legal CNR encounters is assumed to be the same as the stock composition of the legal catch. The stock composition of the shakers and sublegal CNR encounters is estimated using the non-vulnerable portions of the cohorts for stocks that contribute to the landed catch. The procedures used to estimate incidental mortality in the Chinook model have been described by AWG (1991) and CTC (2004).

For some fisheries or years, CWT recoveries are either lacking or cannot be used in certain analyses of this exploitation rate assessment. In some of these situations the model can be used for ER assessment.

### 2.1.2. Brood Year Exploitation Rates

Brood year exploitation rates provide the best measure of the cumulative impact of fisheries upon all age classes of a stock. The rates are computed as the ratio of AEQ total fishing mortality to AEQ total fishing mortality plus escapement. The AEQ factor represents the proportion of fish of a given age that would, in the absence of fishing, subsequently leave the ocean to return to the terminal area on the spawning migration. The numerator may be partitioned into components for AEQ reported catch and AEQ incidental mortality, with each component occurring in either ocean fisheries or freshwater fisheries.

The exploitation rate on an indicator stock may differ from the exploitation rate on the wild stock it represents if the indicator stock is of hatchery origin and subject to terminal fisheries directed at harvesting surplus hatchery production. In the case of the brood exploitation rate, this difference was addressed by computing a rate for ocean fisheries and a total for all fisheries. Ocean fisheries were defined to include marine sport and troll fisheries and CWT recoveries of ocean age 2 and age 3 fish in all non-terminal net fisheries. By partitioning the fisheries in this way, the most appropriate measure of brood exploitation rates on wild stocks could be selected. The method selected for each exploitation rate indicator stock is given in Table 2.2. If broods are incomplete, but have data through age 4 (age 5 for spring stocks), then average maturation rates are applied to predict the completed brood value.

The brood year exploitation rate is calculated as:

$$
B Y E X P_{B Y, F}=\frac{\sum_{a=\text { Minage }}^{\text {Maxage }}\left(\sum_{f \in\{F\}} \text { TotMorts }_{B Y, a, f} * A E Q_{B Y, a, f}\right)}{\sum_{a=\text { Minage }}^{\text {Maxage }}\left(\sum_{f=1}^{\text {Nummisheries }} \operatorname{TotMorts}_{B Y, a, f} * A E Q_{B Y, a, f}+E s c_{B Y, a}\right)}
$$

The Adult Equivalent (AEQ) rate is calculated as:

$$
\begin{aligned}
& \text { AE }_{B Y, a-1, f}=\text { MatRte }_{a-1, B Y}+\left(1-\text { MatRte }_{a-1, B Y}\right) * \text { Surv }_{a} * A E Q_{B Y, a, f} \\
& A E Q_{B Y, M a x a g e, f} \equiv 1.0
\end{aligned}
$$

See Table 2.3 for a description of notation.

### 2.1.3. Brood Year Survival Rates and Indices

The brood year survival of CWT-tagged smolts after release is calculated for most exploitation rate indicator stocks (Table 2.2). This survival rate is frequently referred to as the marine survival of the tag group but also includes any mortality occurring in freshwater following release. Interpretation of this survival rate is stock specific. Two measures of survival indices or
patterns are computed: survival to the age 2 cohort based on CWT recoveries, and the "environmental variable" (EV) determined from the calibration of the Chinook model (described in the following section). The CWT-based estimate is our most direct measure of a brood's survival, but this measure is not available until the brood is complete (i.e., all ages have returned to spawn). The model EV parameter, however, provides a more current measure of the survival rates expected in brood years contributing to present and future fisheries. For CWT data, the survival rate for a stock and brood year is the estimated age 2 cohort (from the cohort analysis) divided by the number of CWT fish released.

        FP a.s.CY,f}= ratio of ER (s,a,f,CY to BPISBMER
    ISBMIdx CY = ISBM index for calendar year CY
    ISBMIdx }\mp@subsup{\}{CY}{}=\mathrm{ ISBM index for calendar year CY
    MatRte a-l,BY}=\mathrm{ maturity rate at next younger age by brood year
    Maxage = maximum age of stock (generally age 6 for stream type stocks, age 5 for ocean
        type stocks)
```

Minage $=$ minimum age of stock (generally age 3 for stream type stocks, age 2 for ocean type stocks)
Morts $_{C Y, a, f}=$ landed or total fishing mortality in year $C Y$ and age $a$ in fishery $f$
$N M_{a}=$ annual natural mortality prior to fishing on age $a$ cohort
Numfisheries $=$ total number of fisheries
$R T_{C Y}=$ ratio of the catch quota in the current year to the catch that would be predicted given current abundance, current size limits, and base period exploitation rates
$s=$ a particular stock
$S=$ set of all stocks that meet selection criteria
$S C_{B Y}=$ ratio of the estimated terminal run and model predicted terminal run for brood year BY
$\operatorname{Surv}_{a}=$ survival rate $\left(1-\mathrm{NM}_{\mathrm{a}}\right)$ by age
TotMorts $_{B Y, a, f}=$ total fishing related mortality for brood year $B Y$ or calendar year $C Y$ or during the base period BPER and age $a$ in fishery $f$
Tot $^{\text {CWTRelease }}{ }_{B Y}=$ number of CWT fish released in the indicator group in brood year $B Y$

$$
\text { Age2CohSurv }_{B Y}=\frac{\text { Cohort }_{B Y, 2}}{\text { TotCWTRelease }_{B Y}}
$$

where Cohort $_{B Y, 2}$ is calculated recursively from the oldest age down to age- 2 using:

$$
\text { Cohort }_{B Y, a}=\frac{\sum_{f=1}^{\text {Nummisheries }^{T o t M o r t s_{B Y, a, f}}+E s c_{B Y, a}+\text { Cohort }_{B Y, a+1}}}{1-N M_{a}}
$$

If ocean age- 5 is absent, the age- 4 cohort size is estimated using the following formula:

$$
\text { Cohort }_{B Y, 4}=\frac{\sum_{f \in \text { Preeerminal }} \text { TotMorts }_{B Y, 4, f}+\frac{\text { Esc }_{B Y, 4}+\sum_{f \in \text { Terminal }} \text { TotMorts }_{B Y, 4, f}}{\text { AvgMatRte }_{4}}}{1-N M_{4}}
$$

### 2.1.4. Stock Distribution Patterns

Brood year exploitation rates can indicate the fisheries that exploit a stock and the rates that occur on a specific brood, but do not indicate the exploitation pattern on a stock during one calendar year (across broods). Stock mortality distributions (reported catch or total) in a calendar year are calculated over all ages in the fisheries (if at least three brood years contribute to recoveries) as follows:

$$
\text { CYDist }_{C Y, F}=\frac{\sum_{a=\text { Minage }}=\frac{\text { Maxage }\{F\}}{} \operatorname{Morts}_{C Y, a, f} * A E Q_{B Y=C Y-a, a, f}}{\sum_{a=\text { Minage }}^{\text {Maxage }}\left(\sum_{f=1}^{\text {Numfisheries }} \operatorname{Morts}_{C Y, a, f} * A E Q_{B Y=C Y-a, a, f}+E s c_{C Y, a}\right)}
$$

It should be noted that catch distributions may not indicate the relative distribution of an indicator stock. For example, closure of a fishery would result in no reported catch but this would not necessarily indicate zero abundance of the stock in that fishing area.

### 2.1.5. Fishery Indices

When the PST was negotiated in 1985, catch ceilings and increases in stock abundance were expected to reduce harvest rates in fisheries. The fishery index (FI) provided a means to assess performance against this expectation. Relative to the base period, an index less than 1.0 represents a decrease from base period harvest rates while an index greater than 1.0 represents an increase. While the determination of allowable catch for AABM fisheries in the 1999 Agreement is different from the original PST catch ceilings, these fishery indices continue to provide a useful index of change in harvest rates in these fisheries. Fishery indices are used to measure relative changes in fishery harvest rates because it is not possible to directly estimate the fishery harvest rates.

Fishery indices are computed in AEQ for both reported catch and total mortality (reported catch plus estimated incidental mortality). The total mortality index provides a consistent means of representing changes in reported catch and incidental mortality, including those associated with regulatory measures such as minimum size limits and CNR periods. Equations used to define the index are shown below.

$$
\begin{aligned}
E R_{s, a, f, C Y} & =\frac{\text { TotMorts }_{s, a, f, C Y} * A E Q_{s, B Y=C Y-a, a, f}}{\text { Cohort }_{s, B Y=C Y-a, a} *\left(1-N M_{a}\right)} \\
F I_{f, C Y} & =\frac{\sum_{s \in\{S S a \epsilon\{A\}} E R_{s, a, f, C Y}}{\left(\frac{\sum_{B P E R=79}^{82} \sum_{s \in\{S\}} \sum_{a \in\{A\}} E R_{s, a, f, B P E R}}{4}\right)}
\end{aligned}
$$

For AABM fisheries, indices are presented for troll gear only although the catch limitations also apply to recreational fisheries and net fisheries in SEAK and the recreational fisheries in NBC and WCVI. As in past years, recoveries from the troll fishery were used because the majority of the catch and the most reliable CWT sampling occur in these fisheries. In addition, there are data limitations in the base period for the sport fisheries. Because the allocation of the catch among gear types has changed in some fisheries (e.g., the proportion of the catch harvested by the sport fishery has increased in the SEAK and NBC fisheries), the indices may not represent the harvest impact of all gear types.

The CTC uses fishery indices to reflect changes in fishery impacts relative to the base period (1979-1982). The form of the fishery index limits inclusion of stocks to those with adequate tagging during the base period, but fishing patterns for some fisheries have changed substantially since then. One example of this is the SEAK troll fishery where the catch during the winter
season has increased, the spring fishery has been largely curtailed, and the summer season has become markedly shorter. Because stock complexes are dynamic throughout the year, stock specific impacts of the SEAK fishery have likely changed over time as season structure has been altered. To incorporate changes in stock composition and to include stocks without base period data, the CTC examined alternative derivations of fishery indices (CTC 1996).

The CTC determined that a useful fishery index should reflect both changes in harvest rates and stock distribution. Three general, desirable characteristics were identified:

1) the index should measure changes in fishery harvest rates if the distribution of stocks is unchanged from the base period;
2) the index should have an expected value of 1.0 for random variation around the base period fishery harvest rate, cohort size, and stock distributions; and
3) the index should weight changes in stock distribution by abundance.

After exploring several alternatives, the CTC concluded that the best estimate for a fishery index would consist of the product of a fishery harvest rate index and an index of stock abundance weighted by average distribution (i.e., the proportion of a cohort vulnerable to the fishery). This assessment supported the application of the stratified proportional harvest rate index adjusted for untagged stocks (SPFI), as presented by Alaska Department of Fish and Game (ADF\&G).
Computation of the SPFI is discussed below.
Initially the CWT harvest rate $\left(h_{t, c y}\right)$ must be set to an arbitrary value between 0 and 1 . Then, the distribution parameter $\left(d_{t, s, a}\right)$ is calculated, and the result is substituted into the second equation below to recursively recalculate $h_{t, c y}$ and subsequently $d_{t, s, a}$. The largest stock-age distribution parameter in a stratum is then set to 1 to create a unique solution. See Table 2.4 for notation description.

$$
\begin{gathered}
d_{t, s, a}=\sum_{C Y} r_{t, C Y, s, a} / \sum_{C Y}\left(h_{t, C Y} * n_{C Y, s, a}\right) \\
h_{t, C Y}=\sum_{s} \sum_{a} r_{t, C Y, s, a} / \sum_{s} \sum_{a}\left(d_{t, s, a} * n_{C Y, s, a}\right)
\end{gathered}
$$

The resulting unique solution is inserted into the following equations to compute the yearly harvest rates for each strata and the overall fishery.

$$
\begin{gathered}
H_{t, C Y}=\left[\left(\sum_{\sum_{s} \sum_{a} c_{t, C Y, s, a}}^{\sum_{s} r_{a} r_{t, C Y, s, a}}\right) *\left(C_{t, C Y}-A_{t, C Y}\right)\right] /\left[\left(C_{t, C Y}-A_{t, C Y}\right) / h_{t, C Y}\right] \\
H_{. C Y}=\sum_{t}\left[\left(\frac{\sum_{s}^{s} \sum_{a} c_{t, C Y, s, a}}{\sum_{s} \sum_{a} r_{t, C Y, s, a}}\right) *\left(C_{t, C Y}-A_{t, C Y}\right)\right] / \sum_{t}\left[\left(C_{t, C Y}-A_{t, C Y}\right) / h_{t, C Y}\right]
\end{gathered}
$$

$$
\begin{gathered}
S_{t, C Y}=H_{t, C Y} / \sum_{C Y=1979}^{1982} H_{t, C Y} \\
S_{. C Y}=H_{. C Y} / \sum_{C Y=1979}^{1982} H_{. C Y}
\end{gathered}
$$

Table 2.4. Parameter definitions for equations used for SPFI in SEAK.

## Parameter $\mid$ Description

$A_{t, C Y}=$ Alaska hatchery origin catch by strata $t$, year $C Y$
$c_{t, C Y, s, a}=$ adult equivalent CWT catch by strata $t$, year $C Y$, stock $s$ and age $a$
$C_{t, C Y}=$ catch by strata $t$, year $C Y$
$d_{t, s, a}=$ distribution parameter by strata $t$, stock $s$ and age $a$
$h_{t, C Y}=$ CWT harvest rate by strata $t$, year $C Y$
$H_{. C Y}=$ harvest rate by year $C Y$
$H_{t, C Y}=$ harvest rate by strata $t$, year $C Y$
$n_{C Y, s, a}=$ CWT cohort size by year $C Y$, stock $s$ and age $a$
$r_{t, C Y, s, a}=$ CWT recoveries by strata $t$, year $C Y$, stock $s$ and age $a$ $S_{. C Y}=$ SPFI by year $C Y$ $S_{t, C Y}=$ SPFI by strata $t$, year $C Y$

### 2.1.6. ISBM Indices

In previous reports, the CTC (1996) proposed a non-ceiling fishery index as a measure of the pass-through provision in the 1985 PST. This index compares an 'expected' AEQ mortality (assuming base period exploitation rates and current stock abundance) with the observed AEQ mortality on a stock within a calendar year, over all non-ceiling fisheries of a party (Table 2.5). Index values less than 1.0 indicate that the exploitation rates have decreased relative to the base period. Under the new Agreement, the CTC is required to continue to use the ISBM indices to measure the performance of ISBM fisheries. Paragraph 4, chapter 3 states:
"4. The Parties agree that in respect of ISBM fisheries:
(a) their intent is that the fisheries shall be managed over time to contribute to the achievement of MSY or other agreed biologically-based escapement objectives;
(b) until such times as the ISBM fisheries are managed to meet those escapement objectives, and unless otherwise recommended by the CTC, the non-ceiling index defined in TCChinook (96)1 (February 15,1996 ) will be used to measure performance of ISBM fisheries;
(c) the non-ceiling index for ISBM fisheries will be computed pre-season based on forecasted abundance and fishing plans and evaluated post season for each of the escapement indicator stocks listed in Attachments I to V to this chapter;
(d) for the purposes of this paragraph, until agreed escapement objectives for the stock groups listed in Attachments I to V to this Chapter have been achieved, Canada and the United States shall reduce by 36.5 and 40 percent respectively, the total adult equivalent mortality rate, relative to the 1979-82 base period, in their respective ISBM fisheries that affect those stock groups. The reduction identified in this sub-paragraph shall be referred to as the "general obligation"."

Table 2.5. Fisheries included in the ISBM index by nation.

| Fisheries Included in ISBM Index |  |
| :--- | :--- |
| United States | Canada |
| Washington/Oregon Ocean Troll | Central BC Troll |
| Puget Sound Northern Net | Strait of Georgia Troll |
| Puget Sound Southern Net | North BC Net |
| Washington Coastal Net | Central BC Net |
| Freshwater Terminal Net | West Coast Vancouver Island Net |
| Washington/Oregon Ocean Sport | Strait of Juan de Fuca Net |
| Puget Sound Northern Sport | Johnstone Strait Net |
| Puget Sound Southern Sport | Fraser Net |
| Freshwater Terminal Sport | Freshwater BC Net |
|  | Strait of Georgia Sport |
|  | Strait of Juan de Fuca Sport |
|  | Freshwater BC Sport |

The formula proposed by the CTC in 1991 and referred to in CTC (1996) for a stock/country combination is:

$$
\begin{aligned}
I S B M I d x_{C Y}= & \frac{\sum_{f \in\{F\}} \sum_{a=\text { Minage }}^{\text {Maxage }}\left(\text { TotMorts }_{C Y, f, a} * A E Q_{B Y=C Y-a, a, f}\right)}{\sum_{f \in\{F\}\}} \sum_{a=\text { Minage }}^{\text {Maxage }}\left(B P I S B M E R_{f, a} * \text { Cohort }_{B Y=C Y-a, a}\right)} \\
\text { BPISBMER }_{f, a}= & \frac{\sum_{B P E R=79}^{82} \frac{\left(\text { TotMorts }_{B P E R, f, a} * A E Q_{B Y=B P E R-a, a, f}\right)}{\text { Cohort }_{B Y=B P E R-a, a}}}{4}
\end{aligned}
$$

Direct application of the CTC model alone or CWT data alone was not possible in the computation of all ISBM indices since fisheries required a finer resolution than the CTC model currently provides or because in some cases terminal fisheries occur that make the estimated CWT-based exploitation rate not representative of the untagged stocks.

In those instances the following methods were used:

1) For 2005, two preseason models, the Fisheries Resource Assessment Model (FRAM) and the Columbia River Harvest Model, were used to predict stock-specific impacts in inside fisheries (Puget Sound net and sport, and the Columbia River net and sport fisheries respectively). These estimated impacts were then used to compute the Chinook model fishery policy (FP) scalars for the corresponding CTC model fisheries.
2) For 2005, many ISBM fisheries or stock/fishery combinations had no preseason predictions of harvest rates and in some cases, no prediction of abundance. In those cases,
a repeat of 2004 harvest rates, or a repeat of 2003 rates if estimates of 2004 were also unavailable, was assumed.
3) In 1999-2005 external estimates of impacts in terminal ISBM fisheries were used to generate FP scalars (for model generated estimates) or to modify estimated CWT recoveries (for CWT-based estimates) for many stocks. This was necessary because terminal impacts on some CWT exploitation rate indicator stocks were not representative of the fishery impacts on the untagged stock of interest.
4) For the CWT-based estimates, some indicator stocks did not have 1979 - 1982 base period recoveries. For these stocks, base period exploitation rates for the model stock associated with the wild stock were used, if available.

Tables 2.6 and 2.7 show which model stock or, CWT exploitation rate indicator stock, was used to represent a wild stock. The tables also summarize the methods (if any) used to compute the FP scalars for the model stocks or to adjust the CWT data for exploitation rate indicator stocks for the computation of the ISBM indices. Table 2.8 shows changes made to fishery mappings used in the exploitation rate analysis.

Table 2.6. Methods for computing FP scalars input to the CTC Chinook Model to produce ISBM indices. See Section 2.1.6 for stock specific methods.

### 2.2. MODEL CALIBRATION

This section describes the calibration data and procedures. For reference, a list of stocks and fisheries in the model is provided in Appendix C. Estimation of the model base period parameters is discussed in detail in the model documentation (Analytic Work Group 1991). For 2005, the model used was the same as used during the Pacific Salmon Treaty negotiations (CLB 9812) but with the exception that the actual catches, escapements, and other data through 2004 were added. In addition, CTC-accepted escapement goals were used where available and the form of the Ricker production function was adjusted for those stocks with newly accepted goals (e.g. Harrison River fall Chinook).

### 2.2.1. Calibration Data

The first step in the annual calibration process is to gather new or revised data and update the appropriate model input files. The frequency of updates depends on the frequency of data changes made by the reporting agencies, the magnitude of the change, and the significance of the change to the current model application. For example, the file containing run size data is updated as preseason forecasts and postseason estimates become available since model predictions are sensitive to preseason forecasts and postseason estimates of terminal runs. Months in which forecasts are made for each stock, and the month the final return estimate becomes available, are presented in Table 2.9.

The model is recalibrated annually to incorporate observed data from the previous year and available abundance forecasts for next year. In addition, recalibration may also occur when significant changes in one or more of the following model input files are made.

BSE (base). This file contains basic information describing the structure of the model, including, but not limited to, the number of stocks, age classes and fisheries, the names of fisheries and the proportion of each age class that was not vulnerable to the gear during the base period, identification of terminal fisheries, stock names and production parameters. This file may be modified annually to incorporate productivity parameters that correspond to new CTC agreed escapement goals.

CEI (ceiling). This file contains historical catch data for the 19 fisheries that are modeled as ceiling or catch quota fisheries (as opposed to fisheries modeled solely through control of exploitation rates) through the most recent fishing season.

CNR (Chinook nonretention). Data used by the model to estimate mortalities during CNR periods are read from the CNR file. The data in the CNR file depends on which method is used to calculate CNR mortality. It may include direct estimates of encounters during the CNR period or indicators of fishing effort in the CNR period relative to the retention period.

Table 2.9. Months when final return estimates are available for the previous year and preseason forecasts of abundance are available for the next fishing year from agencies.

| Model Stock | Month Final Return Estimate Available | Month(s) Forecast Available |

| Oregon Coast | February | February |

${ }^{1}$ A preliminary ocean escapement forecast is released in February. An updated ocean escapement forecast reflecting the ocean fishery option adopted by PFMC is released in April.

ENH (enhancement file). This file contains productivity parameters and smolt production for 13 hatchery stocks and one natural stock (Lower Georgia Strait Naturals) with supplementation. Smolt production is expressed as the deviation from the average production during the model base period; as a result, values in the ENH file can be negative if releases in a given year are less than the average reported for the model base period. Additional discussion of the productivity parameters may be found in the model documentation (Analytic Work Group 1991).

FCS (forecast). Estimates of terminal run sizes or escapements and agency supplied preseason forecasts (Table 2.10) are included in the FCS file. Age-specific information is used for those stocks and years with age data.

FP (fishery policy). This file contains scalars that are specific to year, fishery, stock and age that are applied to base period fishery exploitation rates. The FPs are used to scale fishery exploitation rates relative to the model base period and can be used for a variety of purposes. For example, in the ocean areas off of the Washington and Oregon North of Cape Falcon (WA/OR) troll fishery, the FPs are used to model the differential impacts on Columbia River and Puget Sound stocks as the proportion of the catch occurring in the Strait of Juan de Fuca varies. The source of the FPs is generally the reported catch fishery index computed from CWT data in the annual exploitation rate analysis or the ratios of harvest rates computed from terminal area run reconstructions.

IDL (interdam loss). The IDL file contains stock-specific conversion factors for the Columbia River Summer, Columbia Upriver Bright, Spring Creek Tule, and Snake River Fall stocks provided each year by Columbia River fishery managers. The factors represent the fraction of the stock that can be accounted for after mainstem dam passage in the Columbia River; losses can be attributed to direct mortality at the various dams, mortality in the reservoirs between dams, fallbacks, tailrace spawning, and other factors. The interdam loss factor is equal to one minus the conversion factor.

IM (changes in incidental mortality rates). The IM file contains the incidental mortality rates by fishery for legal and sublegal fish that differ from those used in the base period due to alterations in gear, regulations, or fishery conduct.

MAT (maturity and adult equivalent factors). The MAT file has annual estimates of maturation rates and adult equivalent factors for 11 stocks (AKS, BON, CWF, FRL, GSH, LRW, ORC, RBH, RBT, SPR, URB, and WSH). These estimates replace the base period rates in the BSE file. The annual estimates are obtained from the annual exploitation rate analysis. The average value is used for years beyond the last year for which estimates are available (due to incomplete broods and the one year lag for completion of the annual exploitation rate analysis).

PNV (proportion nonvulnerable). A PNV file is created for each fishery for which a size limit change has occurred since the model base period. Each file contains age-specific estimates of the proportion of fish not vulnerable to the fishing gear or smaller in length than the minimum size limit. The PNVs were estimated from empirical size distribution data; in some instances independent surveys of encounter rates were used to adjust the PNV for age 2 fish to account for the proportion of the cohort that was not vulnerable to the fishing gear.

STK (stock). This file contains the stock and age-specific starting (base period) cohort sizes, the base period exploitation rates on the vulnerable cohort for each model fishery, maturation schedules, and adult equivalent factors. This file is updated if new stocks or fisheries are added, new CWT codes are used to represent distribution patterns of existing model stocks, or a re-
estimation of base period data occurs. Modification of this file will result in a model different from that used in the negotiations (CLB 9812).

The calibration is controlled through a file designated with an OP7 extension.

Table 2.10. Methods used to forecast the abundance of stocks in the PSC Chinook Model. Externally provided forecast type codes are $\mathrm{S}=$ sibling; $\mathrm{R}=$ return rate; $\mathrm{C}=$ model internally estimated projection.

| Model Stock | Forecast Characteristics |  |  | Comments |
| :---: | :---: | :---: | :---: | :---: |
|  | Forecast Type | Preseason Age-specific | Postseason Age-specific |  |
| Alaska South SE | C | - | Yes | Calibrated to escapement |
| North/Central BC | C | - | No | Calibrated to terminal run |
| WCVI Hatchery + Natural (RBH and RBT model stocks) | S | Yes | Yes | Robertson Creek Hatchery forecasts plus expansion for other WCVI stocks based on ratio of terminal run sizes |
| Upper Strait of Georgia | C | - | Partial | Calibrated to escapement |
| Lower Strait of Georgia Hatchery | C | - | Yes | Calibrated to escapement to GSH hatchery systems and Squamish River |
| Lower Strait of Georgia Natural | C | - | Yes | Calibrated to escapement to Cowichan and Nanaimo Rivers |
| Fraser Early | C | - | No | Calibrated to terminal run |
| Fraser Late | S | Yes | Yes | Combined forecasts for Harrison River and Chilliwack Hatchery |
| Nooksack Spring | C | Partial | No | No data since 1987 |
| Nooksack Fall (Samish) | R | No | No | 2001-2002 return rate |
| Snohomish Wild | R | No | No | Recruits per Spawner |
| Skagit Wild | S | Yes | Yes | Cohort return rate |
| Puget Sound Natural Fingerling | R | No | No | Calibrated to terminal run |
| Stillaguamish Wild | R | No | No | Recruits per Spawner |
| Puget Sound Hatchery <br> Fingerling + Yearling | R | No | No | Age-specific forecasts not available for all components |
| Washington Coastal Wild | R | No | No | Calibrated to terminal run |
| Washington Coastal Hatchery | C | No | No | Calibrated to terminal run |
| Cowlitz Spring Hatchery | S | Yes | Yes | Prediction is to mouth of tributary streams. |
| Willamette River Hatchery | S | Yes | Yes | Prediction is to mouth of Willamette River |
| Columbia River Summer | S | No | No | Changed in 2001 to 5-year average |
| Spring Creek Hatchery | S | Yes | Yes | Run reconstruction used to estimate Columbia River mouth return |
| Lower Bonneville Hatchery | S | Yes | Yes | Run reconstruction used to estimate Columbia River mouth return |
| Upriver Brights | S | Yes | Yes | Run reconstruction used to estimate Columbia River mouth return |
| Snake River Wild Fall | C | - | No | Calibrated to escapement to Lower Granite. External forecast is sometimes available. |
| Mid-Columbia River Bright | S | Yes | Yes | Run reconstruction used to estimate Columbia River mouth return |
| Lewis River Wild | S | Yes | Yes | Run reconstruction used to estimate Columbia River mouth return |
| Oregon Coast | S | Yes | Yes | Weighted average age composition from four index rivers |

### 2.2.2. Calibration Procedures

The objective of the calibration is to estimate stock and brood year specific environmental variant (EV) scalars. The calibration uses an iterative algorithm to estimate the EV scalars for each brood year and model stock to account for annual variability in natural mortality in the initial year of ocean residence. EV scalars are applied to production resulting from brood year escapements and the base period spawner-recruit function to produce the age 1 abundance by stock. Fishing impacts and natural mortalities are then applied through model processes. EVs also adjust for biases resulting from errors in the data or assumptions used to estimate the base period parameters for the spawner-recruit function.

EVs are estimated through the following steps for stocks calibrated to age-specific terminal run sizes:
(1) Predicted terminal runs are computed for each year using the input files discussed above and with values of all stock productivity scalars (EVs set equal to 1 ).
(2) The ratio of the observed terminal run and model predicted terminal run $\left(S C_{B Y}\right)$ is computed for each brood year. For example, if the estimated and model predicted terminal runs for the 1979 brood were 900 and 1,500 age 3 fish in 1982, 4,000 and 4,500 age 4 fish in 1983, and 1,000 and 1,500 age 5 fish in 1983, the ratio would be computed as:

$$
\begin{gathered}
S C_{B Y}=\frac{\sum_{a=\text { Minage }}^{\text {Maxage }}(\text { ObservedTerminalRun })_{a}}{\sum_{a=\text { Minage }}^{\text {Maxage }}(\text { ModelPredictedTerminal Run })_{a}} \\
S C_{B Y}=\frac{900+4000+1000}{1500+4500+1500}
\end{gathered}
$$

In the absence of age-specific estimates of the terminal run, the components are computed by multiplying the total terminal run by the model predictions of age composition.
(3) The stock productivity scalar for iteration $n$ and brood year $B Y$ is computed as:

$$
E V_{n, B Y}=E V_{n-1, B Y} * S C_{B Y}
$$

(4) Steps 1-3 are repeated until the absolute change in the stock productivity scalars for all stocks is less than a predetermined tolerance level (currently set at 0.05 ). This value could be changed to a finer or larger resolution if required.

$$
\left|\frac{E V_{n, B Y}-E V_{n-1, B Y}}{E V_{n-1}}\right|<0.05
$$

Several options for the calibration are provided in the OP7 control file. The options include the ability to control the brood years for which the stock productivity scalars are estimated in each iteration and also the type of convergence criteria. For the 2005 calibration, stock productivity scalars were estimated for all brood years in each iteration. Convergence was defined to occur when the absolute value of the difference in stock productivity scalars between successive iterations did not exceed 0.05 .

Stock-specific calibration options are specified in the FCS file and discussed below:
Minimum Number of Age Classes. Data for all age classes will not be available when the stock productivity scalars are estimated for recent broods. Since considerable uncertainty may exist in a single data point, application of the calibration algorithm can be restricted to cases in which a specific minimum number of age classes are present.

Minimum Age. Considerable uncertainty often exists in the estimates of terminal runs or escapements for younger age classes, particularly age 2 . The minimum age class to include in the calibration algorithm is specified in the FCS file.

Estimation of Age Composition. Age-specific estimates of the terminal run or escapement may not be available. An option is provided to estimate the age composition using base period maturation and exploitation rates.

The forecasts provided by the management agencies typically represent terminal runs or escapements without adjustments for changes in ocean fisheries. Since the forecasts implicitly include exploitation in pre-terminal fisheries, the expansion of the forecasts to total cohort size should be made using the average exploitation rate for the period of years in the forecast database.

The 2005 calibration was completed in two stages to facilitate computation of the average exploitation rates and incorporation of the agency forecasts. The Stage 1 calibration provided initial estimates of exploitation rate scalars for fishing years 1979 through 2004 using updated catch and escapement data through 2004. Average exploitation rate scalars were then computed and used as input values for 2004 fisheries in the Stage 2 calibration, except for the WCVI and Fraser Late (FRL) stocks whose forecasts already account for changes in the ocean fisheries.

The average exploitation rate scale factors $(\overline{F P})$ for each model fishery were obtained from the Stage 1 calibration using the following formula:

$$
\overline{F P}_{a, s, C Y, f}=\frac{\sum_{C Y=C Y_{\text {sur }}}^{C Y_{\text {or }}}}{} R T_{C Y} * F P_{s, a, C Y, f},
$$

The range of years used to compute the average varied between stocks and was fishery and agespecific. The input files used in the Stage 2 calibration were identical to those used in Stage 1 with two exceptions:
(1) the average exploitation rate scale factors for each fishery were inserted into the FP file for 2005; and
(2) the Stage 1 EVs were used as starting values for the Stage 2 calibration.

To determine the acceptability of a calibration by the CTC (i.e., whether an annual calibration is deemed final by the CTC), several results are examined:
(1) accuracy of the reconstructed catches in the fisheries (these values will consistently differ from the actual catches if the calibration is not able to recreate exactly the actual catches in the years 1979 through 1984, the model years prior to implementation of the ceiling algorithm);
(2) accuracy of model predicted terminal runs or escapements relative to the data used for calibration of each stock;
(3) comparison of model predicted age structure in terminal runs or escapements with data used for calibration (consistent biases in age structure are addressed by changing maturation rates);
(4) patterns in the stock productivity scalars compared with marine survival patterns generated by the annual exploitation rate analysis;
(5) comparison of CWT and model estimates of fishery harvest rate indices;
(6) comparison of model estimates of mortality distributions for individual stocks to those generated from the annual CWT-based exploitation rate analysis; and
(7) comparison of model estimated AIs with those AIs estimated by model CLB 9812.

Calibration usually involves an iterative process until a judgment is made by the CTC that an acceptable fit to all the data was achieved. This decision usually involves an inspection and trial-and-error process. The determination of whether or not further calibrations are necessary is based principally on the significance of deviations from observed or estimated values for stocks and fisheries most relevant to the issues to be evaluated and on the time constraints established for completion of the calibration.

### 2.2.3. Changes from Previous Calibration Procedures

### 2.2.3.1. Changes in the Model

No changes were made to the model for 2005.

### 2.2.3.2. Data Changes Involved in the Exploitation Rate Analysis

1. In 2003, the catch sample expansion had an error in weeks 38 and 39 that was over expanding recoveries of Chinook in the Columbia River net fisheries (expansions of 81 and 37 (rounded) fish respectively). We contacted Doug Case (ODFW, Clackamas office) to get the actual catches and samples in that week. Expansions were recalculated as 2.92 and 5.53 for weeks 38 and 39 respectively to estimate the overall catches in the Columbia River gillnet fisheries.
2. Oregon Salmon River escapement recoveries were missing in 2003. John Leppink (ODFW) sent us the recoveries externally and we incorporated these numbers. It appears
that the numbers reported are underestimates (as the expansion factors of fish sampled from the spawning grounds seems to be extremely low, <2). In addition, an analysis of the distribution files indicates that the percentages are about a third of what is normally observed in the escapement.
3. Missing data for the 2001 and 2002 Columbia River net recoveries were not rectified as the data were not available in RMIS.

### 2.2.3.3. Changes to the Input Data for the Chinook Model

1. Upper Georgia Strait, Northern British Columbia, Lower Georgia and Georgia Strait Hatchery postseason runs were updated to match the DFO external FPA files.
2. Upper Columbia Summer stocks were changed to match TAC database on Upriver Summers (the Upriver Summer component on the Columbia has been separated from the Snake River component).
3. Stillaguamish forecast was not used in the run.
4. Escapements for RBT in 2004 were corrected in the FCS file and the 2005 RBT forecast and historical time series of escapements by age were corrected.
5. The time series of Washington Coastal hatchery escapements was corrected as well as the Washington Coastal terminal FPs.
6. The entire time series of escapement data for the Northern Oregon Coastal stock was changed.

### 2.3. GENERAL FORECAST METHODS

For those stocks with externally provided forecasts of abundance in 2005, management agencies used two general methods to predict terminal returns or escapements:

Sibling Models. Empirical relationships between abundance (commonly measured as terminal run size) of age $a$ fish in calendar year $C Y$ and the comparable abundance of age $a+1$ fish in year $C Y+1$ are used to predict abundance in 2005 from data collected in previous years (forecast type S in Table 2.9).

Average Return Rate Models. Return rates of adults by age from smolts or parents are averaged over past brood years, then these averages are used to discount abundance of smolts or parents for brood years that will be exploited in 2005 (forecast type R in Table 2.9).

A more detailed description of the forecast methods used for specific stocks is found in Appendix D.

## 3. RESULTS

### 3.1. EXPLOITATION RATE ANALYSIS

### 3.1.1. Brood Year Exploitation Rates

Brood year exploitation rates for 23 stocks were computed (Appendix F, Figures F.1-F.23). These figures are presented as cumulative bar graphs with landed catch plus incidental mortality (non-landed catch mortality due to fishing) summing to the total mortality for each brood year. Figures labeled as ocean mortality exclude terminal fishery mortality because the terminal fishery is directed at harvesting only surplus hatchery production, while total mortality indicates ocean plus terminal fishery mortality. In general, exploitation rates for these stocks have declined from the base period years.

### 3.1.2. Survival Indices

Estimated total brood year survival from CWT exploitation rate analysis and EV scalars from the model are presented for 30 of the index stocks in Appendix E. In general, recent brood year survivals are lower than in earlier years of the time series for completed brood years. For some stocks, survivals for recent incomplete broods have been increasing. Correlation coefficients ( $r$ values) were computed as a measure of association between the two indices of survival (Table 3.1). A correlation approaching 1.0 indicates a strong linear relationship and provides evidence that the EV is predictive of the final cohort survival. Conversely, a correlation approaching 0 indicates little relationship between the EV scalar and final cohort survival. The degree of correlation varied substantially among stocks. Of the 30 stocks, 18 had $r$ values that were significantly different from zero ( $P<0.05$ ). Correlation coefficients for these 18 stocks ranged from 0.46 to 0.82 .

Table 3.1. Correlation coefficient $(r)$ between total brood year survivals estimated from CWTs and EV scalars for 30 stocks. $N$ is the number of brood years with survival and EV data; $P$ is the probability that the true $r$ is equal to 0 . A low $P$ value indicates a significant correlation.

| Exploitation Rate Indicator Stock | $\mathbf{N}$ | $\mathbf{r}$ | $\mathbf{P}$ |
| :--- | :---: | :---: | :---: |
| Alaska Spring | 20 | 0.37 | 0.113 |

| Salmon River | 20 | 0.54 | 0.014 |

### 3.1.3. Stock Distribution

Tables in Appendix G provide the distribution of a stock's catch mortality among fisheries, as well as escapement, for both reported catch and total mortality in a calendar year. The distribution is shown as a percentage of the annual production; values within a year sum to $100 \%$.

### 3.2. MODEL OUTPUT

### 3.2.1. AABM Abundance Indices and Associated Catches

Beginning with the 1999 fishing season, the Agreement specified that the AABM fisheries are to be managed through the use of the preseason AIs, where specific allowable harvest corresponds to a given AI for each fishery. The preseason AIs that were used to establish harvest management targets are summarized in Table 3.2. The Agreement also stipulated the AIs could be adjusted in season using CTC approved methodologies. This has been invoked only once, in 1999, when an inseason AI of 1.14 was used instead of the preseason AI of 1.10 for SEAK. The 2005 AI for the SEAK troll fishery is 2.05 , for the NBC troll fishery it is 1.69 , and for the WCVI troll fishery is 0.88 .
Table 3.2. Abundance indices for 1999 to 2005 for the SEAK, NBC, and WCVI troll fisheries.

|  | SEAK |  | NBC |  | WCVI |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Preseason | Postseason | Preseason | Postseason | Preseason | Postseason |

| 2002 | 356,500 | 371,900 | 357,133 | 192,700 | 237,800 | 150,137 | 203,200 | 196,800 | 165,036 |
| 2003 | 366,100 | 439,600 | 380,152 | 197,100 | 277,200 | 191,657 | 181,800 | 268,900 | 175,821 |
| 2004 | 383,500 | 418,300 | $\begin{gathered} 428,773 \\ 433,446^{2} \end{gathered}$ | 243,600 | 267,000 | 241,508 | 192,500 | 209,600 | 216,166 |
| 2005 | 416,400 |  |  | 246,600 |  |  | 188,200 |  |  |

${ }^{1}$ Nomenclature is T for troll, S for sport and N for net.
${ }^{2}$ The lower value results from subtracting a terminal exclusion catch for the Stikine River in 2004, which is in dispute.

Figure 3.1. Preseason allowable catches (open circles) and postseason catches (diamonds) in Southeast Alaska AABM fisheries, 1999-2004.

Figure 3.2. Preseason allowable catches (open circles) and postseason catches (diamonds) in Northern British Columbia troll and Queen Charlotte Islands recreational AABM fisheries, 19992004.

Figure 3.3. Preseason allowable catches (open circles) and postseason catches (diamonds) in West Coast Vancouver Island AABM fisheries, 1999-2004.

### 3.2.1.1. Stock composition of AABM fisheries, 1979-2005

There are 30 stocks used in the model. However, the majority of catches in AABM fisheries are often composed of only a few major stocks (Figures 3.4 through 3.6). The relative abundance for each major stock is shown in the following graphs (see Appendix I for tabular results). A time series of abundance estimates for each of the 30 model stocks in each AABM fishery based on the 2005 CTC calibration (CLB 0506) are shown in Appendix J and H, respectively. In general, AIs had a peak during the late 1980s and another in 2003.

Figure 3.4. Total abundance indices for the Southeast Alaska troll fishery with annual stock composition indicated by abundance indices for major model stocks from CLB 0506.
The major model stocks contributing to the SEAK AIs, on average, are: WCVI Natural and Hatchery, Upriver Brights, North/Central BC, and Oregon Coastal (Figure 3.4). The 2005 forecast for the Columbia Upriver Bright stock is slightly lower compared to the 2004 postseason assessment. The "other" category is primarily Upper Georgia Strait, Columbia River Summers and Mid Columbia River Brights.

Figure 3.5. Total abundance indices for the Northern BC troll fishery with annual stock composition indicated by abundance indices for major model stocks from CLB 0506.

The major model stock groups in the NBC AABM fishery are WCVI Natural and Hatchery, Upriver Brights, Oregon Coastal, North/Central BC, and Washington Coastal Wild and Hatchery (Figure 3.5). The 2005 preseason AI is noticeably lower compared to the 2004 postseason AI.

Figure 3.6. Total abundance indices for the WCVI troll fishery with annual stock composition indicated by abundance indices for major model stocks from CLB 0506.

The major model stock groups in the WCVI fishery are: Fraser Late, Puget Sound, Upriver Brights, and Columbia River Tules (Figure 3.6). The 2005 forecast is for lower abundances of Fraser Late, Upriver Brights, and "Other". The "Other" category is similar in both years and is comprised primarily of Columbia River lower river hatcheries, Columbia River summers, Mid Columbia River Brights and Oregon Coastal fish.

### 3.2.2. Overages and Underages

The Agreement specified that the first postseason calibration is used to generate the final estimate of allowable catch for the purpose of tracking overage and underage provisions. The CTC did not produce a final calibration in 2000, thus the 2001 calibration (CLB 0107) was used to generate final AIs for both 1999 and 2000. The first postseason AIs used to evaluate overage and underage are summarized in Table 3.2.

The overage/underage provisions apply to both AABM and ISBM fisheries. However, the CTC identified, in a February 12, 2002 letter to the PSC, major technical obstacles and policy concerns for adjusting harvest levels in response to overage and underages. The major problem identified for AABM fisheries is the confounding of forecast and management error in assessing overages and underages. Forecast error is associated with the accuracy of the preseason AIs (Table 3.2) that is used to determine the preseason estimate of allowable catch. Management error is related to the harvest manager's ability to attain the preseason estimates of allowable catch. Harvest managers have no prior knowledge of the postseason estimate of allowable catch, which can be quite different from the preseason estimate (Table 3.3).

Evaluation of overage/underage in ISBM fisheries is even more problematic than in the AABM fisheries. Final evaluation using CWT-based estimates of exploitation cannot be carried out until several years after fisheries have occurred, and the tag recoveries for all ages of a cohort are complete. Preseason estimates of ISBM indices are projected using the model. Model-based and CWT-based estimates of the indices, while generally exhibiting similar trends, are not consistent enough to evaluate small differences in exploitation rates. Even when CWT recoveries are complete for a cohort, because of low tagging rates or low base period exploitation rates, the calculated ISBM indices may lack the statistical power to determine whether or not an overage or underage has actually occurred.

Until an approach for full implementation of overage/underage provisions has been developed and accepted by the PSC, the Commissioners have instructed the CTC to track overages and underages relative to agreed-upon harvest objectives.

### 3.2.3. AABM Fisheries

Table 3.4 shows the differences between the postseason allowable catches and the observed catches in AABM fisheries for 1999-2004, and the cumulative differential for those years. All three AABM fisheries have cumulative underages. In SEAK, observed catches have been below final allowable catches for three of the six years; the cumulative differential is $-5.7 \%$ or $-5.4 \%$. In NBC, observed catches have been below the final allowable catches in all six years; the cumulative differential is $-37.4 \%$. In WCVI, observed catches have been below allowable catches in four of the six years; the cumulative differential is $-19.9 \%$.

Table 3.4. Deviations in numbers of Chinook salmon and percentages from catch targets derived from the first postseason AI (Table 3.2) for Pacific Salmon Treaty AABM fisheries in 1999 to 2003.

| Year | SEAK |  | NBC |  | WCVI |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number of <br> Fish | Percent <br> Difference | Number of <br> Fish | Percent <br> Difference | Number of <br> Fish | Percent <br> Difference |
|  | $+14,642$ | $+7.9 \%$ | $-39,374$ | $-31.2 \%$ | $-70,587$ | $-66.0 \%$ |
| 2000 | $+7,993$ | $+4.5 \%$ | $-91,600$ | $-74.2 \%$ | $+15,238$ | $+17.7 \%$ |
| 2001 | $-63,381$ | $-25.3 \%$ | $-115,400$ | $-72.6 \%$ | $-27,830$ | $-19.1 \%$ |
| 2002 | $-14,767$ | $-4.0 \%$ | $-87,663$ | $-36.9 \%$ | $-31,764$ | $-16.1 \%$ |
| 2003 | $-59,448$ | $-13.5 \%$ | $-85,543$ | $-30.9 \%$ | $-93,097$ | $-34.6 \%$ |
| 2004 | $+10,488$ | $+2.5 \%$ |  |  |  |  |
| $+15,146$ | $+3.6 \%$ | $-25,492$ | $-9.5 \%$ | $+6,566$ | $+3.1 \%$ |  |
| Cum. | $-104,488$ | $-5.7 \%$ |  |  |  |  |
| $-99,815{ }^{1}$ | $-5.4 \%$ | $-445,072$ | $-37.4 \%$ | $-201,456$ | $-19.9 \%$ |  |

${ }^{\text {I }}$ The lower value results from subtracting a terminal exclusion catch for the Stikine River in 2004, which is in dispute.

### 3.2.4. ISBM Indices by Stock

For ISBM fisheries, the Agreement specifies that Canada and the United States will reduce base period exploitation rates on specified stocks by $36.5 \%$ and $40 \%$, equivalent to ISBM indices of $63.5 \%$ and $60 \%$ percent, respectively. This requirement is referred to as the 'general obligation' and does not apply to stocks that achieve their CTC agreed escapement goal. Estimated ISBM fishery indices are shown in Table 3.5 for Canadian fisheries and Table 3.6 for U.S. fisheries. Both tables present CWT-based indices for 2003, and Chinook model-based predicted indices for 2005. The agreement specifies that the indices for postseason assessment be assessed using the CWT-based estimates, 2003 is the most recent analysis available. CWT-based indices for 19992003 and model-based indices for 1999-2005 are presented in Appendix B.

### 3.2.5. CWT-based Indices in 2003

Canadian ISBM indices from the CWT-based estimates for 2003 were reduced more than required under the agreement for all stocks or stock groups (Table 3.5).

For the Canadian ISBM indices (Table 3.5) several inconsistencies were identified in the way indices had been computed in the past (footnotes 4-9 in Table 3.5). Most of them were inconsistencies between the way indices had been calculated by the model and in the CWT analysis. However, in the case of Lower Georgia Strait, Nanaimo was dropped from the CWTbased index because of concern about the adequacy of base-period data. In addition, Nanaimo and Cowichan stocks are no longer reported separately in the model-based index because there is no way to split the two stocks in the base period.

Thirteen of the 15 U.S. ISBM indices for the CWT-based estimates for 2003 exceeded the limit of $0.60(60 \%)$ established under the agreement (Table 3.6). However, of the 13 U.S. CWT-based ISBM indices that exceeded 0.60 , only 3 (Cowichan, Nanaimo, and Green River) do not have agreed escapement goals, and all stocks with agreed escapement goals met their goals in 2003 (Table 3.10).

### 3.2.6. Predicted ISBM Indices for 2005

Model projected indices (Table 3.5 and Table 3.6) show that the Canadian ISBM fisheries are expected to increase harvest in response to overall abundance with projected indices being slightly over 0.635 for Canadian stocks other than Lower Strait of Georgia, and Fraser Late (Table 3.5). Canadian indices for most U.S. stocks are projected to be below 0.635 ; two of the three stocks projected to be above 0.635 have an agreed escapement goal. In the southern US fisheries (Table 3.6) some stocks are projected to have ISBM index values over 0.60 , but with the exception of Snohomish, the stocks with projected ISBM indices greater than 0.60 have agreed escapement goals and have been meeting these goals. Figures 3.7 and 3.8 show the historical ISBM indices based on CWT recoveries.

Table 3.5. Canadian 2003 ISBM indices based on CWT and the 2005 indices predicted from the PSC Chinook Model.

|  |  | Canadian ISBM Indices |  |
| :---: | :---: | :---: | :---: |
| Stock Group | Escapement Indicator Stock | CWT Indices for 2003 | Model Indices for 2005 |
| Lower Strait of Georgia | Cowichan <br> Nanaimo | $\begin{gathered} 0.363^{1,4} \\ \text { NA }^{5} \end{gathered}$ | $0.381{ }^{6}$ |
| Fraser Late | Harrison River ${ }^{2}$ | $0.055^{7}$ | 0.332 |
| North Puget Sound Natural | Nooksack | 0.046 | 0.314 |
| Springs | Skagit | NA | 0.314 |
| Upper Strait of Georgia | Klinaklini, Kakweikan, Wakeman, Kingcome, Nimpkish | 0.006 | 0.649 |
| Fraser Early (spring and summers) | Upper Fraser, Mid Fraser, Thompson | NA | 0.654 |
| West Coast Vancouver Island Falls | WCVI (Artlish, Burman, Kauok, Tahsis, Tashish, Marble) | $0.496{ }^{8}$ | 0.728 |
| Puget Sound Natural SummerFalls | Skagit | NA | 0.465 |
|  | Stillaguamish | NA | 0.587 |
|  | Snohomish | NA | 0.457 |
|  | Lake Washington | NA | $0.497{ }^{9}$ |
|  | Green River | 0.328 | $0.497{ }^{9}$ |
| North / Central B. C. | Yakoun, Nass, Skeena, Area 8 | NA | 0.680 |
| Washington Coastal Fall Naturals ${ }^{3}$ | Hoko, Grays Harbor, Queets ${ }^{2}$, Hoh ${ }^{2}$, Quillayute ${ }^{2}$ | NA | 0.457 |
| Columbia River Falls ${ }^{3}$ | Upriver Brights ${ }^{2}$ | NA | 0.640 |
|  | Deschutes | NA | 0.640 |
|  | Lewis ${ }^{2}$ | NA | 0.546 |
| Columbia R Summers ${ }^{3}$ | Mid-Columbia Summers ${ }^{2}$ | NA | 0.406 |
| Far North Migrating OR Coastal Falls ${ }^{3}$ | Nehalem ${ }^{2}$, Siletz ${ }^{2}$, Siuslaw ${ }^{2}$ | NA | 0.674 |

${ }^{1}$ Not available (NA) because of insufficient data (lack of stock specific tag codes, base period CWT recoveries, etc).
${ }^{2}$ Stock or stock group with an agreed CTC escapement goal.
${ }^{3}$ Stock group listed in Annex 4, Chapter 3, Attachment V.
${ }^{4}$ An inconsistency was discovered between the approaches used to calculate the model-based and CWT-based indices. The former included harvest rates for terminal sport while the latter did not. Terminal sport harvest rates are now included in the calculation of both indices. Further review is yet required to determine whether the base period terminal sport harvest rates obtained from analyses of Big Qualicum CWT recoveries adequately represent impacts that would have occurred on Cowichan Chinook.
${ }^{5}$ Several problems have been identified in the approach previously used to calculate the CWT-based indices for Nanaimo Chinook. Until these problems are resolved, indices for this stock will not be reported.
${ }^{6}$ Although model-based indices were previously calculated separately for Cowichan and Nanaimo, these did not adequately represent impacts on either LGS stock because the model-based data represent an aggregate of the two stocks and methods do not currently exist to correctly disaggregate these data for calculation of the ISBM values. Until such methods are developed, a single index value only will be reported representing the aggregate.
${ }^{7}$ The terminal sport harvest rates for Chilliwack Hatchery Chinook, the indicator stock, were removed from the calculation for the Harrison River naturals because sport harvest has been essentially zero on the natural population.
${ }^{8}$ An inconsistency was discovered between the approaches used to calculate the model-based and CWT-based indices. The former included harvest rates for terminal sport while the latter did not. Terminal sport harvest rates are now included in the calculation of both indices. A more extended review of the indices for WCVI Chinook will be carried out to determine whether they adequately represent impacts on the WCVI wild aggregate.
${ }^{9}$ For Canadian ISBM fisheries, the Lake Washington and Green stocks are assumed to have the same distribution and index value.

Table 3.6. U.S. 2003 ISBM indices based on CWT and the 2005 indices predicted from the PSC Chinook Model. Order of the stock groups correspond to Annex 4, Chapter 3, Attachment V of the PST 1999 Revised Annexes.

|  |  | U.S. ISBM Indices |  |
| :---: | :---: | :---: | :---: |
| Stock Group | Escapement Indicator Stock | CWT Indices for 2003 | Model Indices for 2005 |
| Washington Coastal Fall Naturals | Hoko | NA ${ }^{1}$ | 0.444 |
|  | Grays Harbor | 0.150 | 0.222 |
|  | Queets ${ }^{4}$ | 0.850 | 1.023 |
|  | Hoh ${ }^{4}$ | 1.340 | 1.499 |
|  | Quillayute ${ }^{4}$ | 0.990 | 1.133 |
| Columbia River Falls | Upriver Brights ${ }^{4}$ | 1.430 | 0.734 |
|  | Deschutes | 0.490 | 0.483 |
|  | Lewis ${ }^{4}$ | 1.030 | 1.058 |
| Puget Sound Natural Summer / Falls | Skagit | NA | 0.195 |
|  | Stillaguamish | NA | 0.185 |
|  | Snohomish | NA | 0.891 |
|  | Lake Washington | NA | 0.373 |
|  | Green R | 1.030 | 0.202 |
| Fraser Late | Harrison River ${ }^{4}$ | 0.640 | 0.670 |
| Columbia R Summers | Mid-Columbia Summers ${ }^{4}$ | 10.040 | 0.545 |
| Far North Migrating OR Coastal Falls | Nehalem ${ }^{4}$ | 3.110 | 2.090 |
|  | Siletz ${ }^{4}$ | 1.590 | 1.233 |
|  | Siuslaw ${ }^{4}$ | 3.820 | 2.643 |
| North Puget Sound Natural | Nooksack | NA | 0.222 |
| Springs | Skagit | NA | 0.213 |
| Lower Strait of Georgia ${ }^{3}$ | Cowichan, | 4.990 | 0.407 |
|  | Nanaimo | 4.990 | 0.407 |
| Upper Strait of Georgia ${ }^{3}$ | Klinaklini, Kakweikan, Wakeman, Kingcome, Nimpkish | NA | NC ${ }^{2}$ |
| Fraser Early (spring and summers) | Upper Fraser, Mid Fraser, Thompson | NA | 0.257 |
| West Coast Vancouver Island Falls ${ }^{3}$ | WCVI (Artlish, Burman, Kauok, Tahsis, Tashish, Marble) | NA | 0.290 |
| North / Central B. C. ${ }^{3}$ | Yakoun, Nass, Skeena, Area 8 | NA | NC |

${ }^{1}$ NA means not available because of insufficient data (lack of stock specific tag codes, base period CWT recoveries, etc).
${ }^{2} \mathrm{NC}$ means that the current model assumes the stock is not caught in U.S. ISBM fisheries.
${ }^{3}$ Stock group listed in Annex 4, Chapter 3, Attachment IV.
${ }^{4}$ Stock with an agreed CTC escapement goal.

Figure 3.7. ISBM indices for Canadian fisheries for 1999-2003. Stocks in bold have CTC agreed escapement goals. The solid horizontal line is an index value of 0.635 .

Figure 3.8. ISBM indices for U.S. fisheries for 1999-2003. Stocks in bold have CTC agreed escapement goals. Note that three index values are not shown on the graph above: Mid-Columbia Summers for 2002 (7.250) and 2003 (10.040) and Cowichan/Nanaimo for 2001 (11.350). The dashed horizontal line is an index value of 0.60 .

### 3.3. MODEL CALIBRATION EVALUATION

The model catches and stock escapements or terminal run sizes estimated by CLB 0506 were evaluated by calculating the average deviations of the model estimates from the observed values (Table 3.7 for the fisheries that are modeled as operating under catch ceilings or quotas for past years, and Table 3.8 for terminal run size/escapements by model stocks).

The model does not estimate catches with equal accuracy in every fishery. This may reflect inadequate representation of the stocks by base period tag data, incomplete representation of the fishery by model stocks, or errors in the estimation of initial stock abundances used to initiate the model. This has been a consistent problem for certain fisheries and cannot be corrected without a base period recalibration. The effect of these deviations depends on the direction of the error (over- or under-estimation), magnitude of the catches, and the stocks contributing to each fishery.

The model catch as a proportion of the true catch is determined by comparing the 1979-1984 model estimated catches by fishery with the actual catches for those years. It is a measure of the proportion of the total catch in the fishery that can be explained by stocks in the model. This proportion is calculated by the model and only applies to the fisheries that are present in the ceiling file.
Table 3.7. Average proportion of observed catch by CLB 0506 for PST fisheries.

| Model Fishery | Model Catch as Proportion <br> of Observed Catch |
| :---: | :---: |
| Southeast Alaska Troll | 0.841 |
| Northern BC Troll | 0.954 |
| Central BC Troll | 1.022 |
| WCVI Troll | 0.857 |
| Washington/Oregon North of Falcon Ocean Troll | 1.152 |
| Strait of Georgia Troll | 0.875 |
| Southeast Alaska Net | 0.600 |
| Northern BC Net | 0.662 |
| Central BC Net | 1.086 |
| Puget Sound North Net | 0.773 |
| Southeast Alaska Sport | 0.758 |
| QCI Sport | 2.902 |
| WCVI Sport | 0.468 |
| Washington/Oregon North of Falcon Ocean Sport | 0.896 |
| Puget Sound North Sport | 0.894 |
| Puget Sound South Sport | 0.595 |
| Strait of Georgia Sport | 1.346 |

The ability of the model to estimate escapements and terminal run sizes varies between stocks. The last four columns of Table 3.8 present summary statistics on the fit achieved by CLB 0506. The column entitled "Average" represents the 1979-2004 average ratios between the modelgenerated estimate and reported escapement or terminal run size. On average, the model accurately estimates the observed terminal run or escapements used in the calibration process.

Table 3.8. Comparison of model calibration results with estimated terminal run sizes or escapements from 1979 to 2004. For most stocks (or stock groups) included in the model calibration, $n=26$ years, except for Nooksack Springs, $(\mathrm{n}=9$, years 1980-1987) and the MidColumbia River Bright Hatchery group ( $\mathrm{n}=24$, years 1981-2004).

| Model Stock | Ratio of: | Average | SD | Min. | Max. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Alaska South SE | Escapement | 1.033 | 0.208 | 0.749 | 1.522 |
| North/Central BC | Term. Run | 1.013 | 0.096 | 0.805 | 1.261 |
| WCVI Hatchery \& Natural | Term. Run | 1.023 | 0.171 | 0.705 | 1.640 |
| Upper Strait of Georgia | Escapement | 1.073 | 0.295 | 0.745 | 2.144 |
| Lower Strait of Georgia Hatchery | Term. Run | 1.007 | 0.160 | 0.665 | 1.373 |
| Lower Strait of Georgia Natural | Escapement | 1.045 | 0.214 | 0.726 | 1.534 |
| Fraser Early | Term. Run | 1.015 | 0.092 | 0.856 | 1.169 |
| Fraser Late | Escapement | 1.000 | 0.137 | 0.756 | 1.222 |
| Nooksack Spring | Escapement | 1.059 | 0.216 | 0.860 | 1.537 |
| Nooksack Fall (Samish) | Term. Run | 1.036 | 0.154 | 0.777 | 1.286 |
| Snohomish Wild | Term. Run | 1.022 | 0.135 | 0.816 | 1.324 |
| Skagit Wild | Term. Run | 1.058 | 0.265 | 0.717 | 1.822 |
| Puget Sound Natural Fingerling | Term. Run | 1.032 | 0.164 | 0.812 | 1.371 |
| Stillaguamish Wild | Escapement | 1.054 | 0.218 | 0.740 | 1.684 |
| Puget Sound Hatchery Fingerling \& Yearling | Term. Run | 1.023 | 0.113 | 0.822 | 1.220 |
| Washington Coastal Wild | Term. Run | 1.030 | 0.150 | 0.809 | 1.403 |
| Washington Coastal Hatchery | Term. Run | 1.043 | 0.174 | 0.817 | 1.453 |
| Cowlitz Spring Hatchery | Term. Run | 1.041 | 0.197 | 0.633 | 1.547 |
| Willamette River Hatchery | Term. Run | 1.008 | 0.125 | 0.783 | 1.317 |
| Columbia River Summer | Term. Run | 1.020 | 0.118 | 0.851 | 1.383 |
| Lower Bonneville Hatchery | Term. Run | 1.044 | 0.281 | 0.656 | 2.082 |
| Cowlitz Fall Hatchery | Term. Run | 1.005 | 0.191 | 0.660 | 1.408 |
| Spring Creek Hatchery | Term. Run | 1.010 | 0.092 | 0.850 | 1.224 |
| Upriver Brights | Term. Run | 1.014 | 0.122 | 0.796 | 1.246 |
| Lyons Ferry | Escapement | 1.141 | 0.537 | 0.522 | 2.974 |
| Mid-Columbia River Bright | Term. Run | 1.032 | 0.171 | 0.765 | 1.474 |
| Lewis River Wild | Term. Run | 1.010 | 0.148 | 0.830 | 1.358 |
| Oregon Coast | Escapement | 1.048 | 0.221 | 0.681 | 1.563 |

There is variability in the annual ratios of model predictions to observed estimates, as can be judged by the standard deviations and ranges. The variability tends to be greatest in less abundant model stocks or in those with highly variable marine survivals. Since the variability is not consistently related to specific stocks, the most likely impacts are annual variations in agespecific survival rates (i.e., random error in estimates of abundance).

The columns entitled "Min" and "Max" are the extreme ranges of annual fits from 1979 through 2004 and represent the smallest and largest ratios between the agency supplied value and the
model estimate, respectively. The significance of these deviations depends upon the questions being evaluated. For example, a large deviation for a stock during the first few years of the calibration or for a stock that has a minor impact on a fishery of concern may not necessitate further attempts at model calibration.

Fishery mortality indices generated by CLB 0506 can be compared to the CWT-based exploitation rate analysis. Model and CWT-based fishery mortality indices use the same equation, but the former are derived from model estimates of catch for all model stocks instead of CWT recovery data from specific exploitation rate indicator stocks.

The CWT fishery mortality indices are considered to be the most accurate, and a comparison of these estimates with those derived from the model provides one measure of how well the model represents fisheries. Two types of fishery indices are presented; reported catch and total mortality. Correlation coefficients between the CWT and model estimates for each type of index for the three AABM troll fisheries (Table 3.9) were all significant ( $\mathrm{P}<0.01 ; \mathrm{n}=25$ years). The model results are closely associated with the CWT-based indices and changes in fishery exploitation rates as indicated in Figures 3.9 through 3.14.
Table 3.9. Correlation coefficients between CWT and model fishery indices for landed catch and total mortality in the AABM troll fisheries.

|  | AABM Troll Fishery |  |  |
| :---: | :---: | :---: | :---: |
|  | SEAK | NBC | WCVI |
| Landed Catch <br> Mortality | 0.896 | 0.870 | 0.924 |
| Total Mortality | 0.806 | 0.868 | 0.927 |

The SEAK fishery mortality index from the model closely follows the trend of the CWT derived estimate from 1979 through 1987 for both landed catch and total mortality (Figures 3.9 and 3.10). Between 1989 and 2000, the model estimate of both landed catch and total mortality indices is less than the CWT-derived estimate for most years but since 2001, the model estimate is noticeably higher. Since 1990, the model estimates also show less variability compared to the CWT-derived indices.

Figure 3.9. Estimated CWT (through 2003) and model landed catch fishery indices (through 2004) for the SEAK troll fishery.

Figure 3.10. Estimated CWT (through 2003) and model total mortality fishery indices (through 2004) for the SEAK troll fishery.

The model-derived fishery mortality indices for NBC generally follow the same trend as CWTderived indices (Figures 3.11 and 3.12). However, since 1991, the model-based estimates have exceeded the CWT-derived estimates in all but four years for both landed catch and total mortality indices.

Figure 3.11. Estimated CWT (through 2003) and model landed catch fishery indices (through 2004) for the NBC troll fishery.

Figure 3.12. Estimated CWT (through 2003) and model total mortality fishery indices (through 2004) for the NBC troll fishery.

Since the base period, the model-derived landed catch fishery index estimates and trends for the WCVI troll fishery have been similar to those derived from CWTs. However, from 1987 through 1995, the model estimates are consistently greater than the CWT-based estimates (Figures 3.13
and 3.14). Starting in 2000, model and CWT estimates have diverged significantly for both landed catch and total mortality.

Figure 3.13. Estimated CWT (through 2003) and model landed catch fishery indices (through 2004) for the WCVI troll fishery.

Figure 3.14. Estimated CWT (through 2003) and model total mortality fishery indices (through 2004) for the WCVI troll fishery.

### 3.4. SUMMARY OF AGENCY STOCK FORECASTS USED IN THE MODEL

A summary of model produced and agency provided forecasts from 1999-2005 is shown in Table 3.10. A major factor influencing how well the model can predict Chinook abundance in AABM fisheries is how well the model can predict the returns of Chinook (in terms of ocean escapement or spawning escapement) in the forecast year. During model calibration, agency forecasts are input to the model for all model stocks for which forecasts are available. Thus, for model stocks with external forecasts, the variation between model forecasts and actual returns can be broken into two parts - the ability of the model to match the input agency forecasts, and the ability of the agency forecasts to accurately predict the actual return of Chinook in the upcoming year. In Table 3.10, the column labeled 'Model Fcst/Agency Fcst' shows the absolute percentage deviation of the model prediction of the return from the agency provided total return. The column labeled 'Agency Fcst/Postseason' shows the absolute percentage deviation of the agency forecast from the actual return. The column furthest to the right, labeled 'Model Fcst/Postseason', shows the absolute percentage deviation of the model prediction of the return from the observed return.

In general, the model does a very good job of matching the agency-supplied forecasts (average error $=-0.7 \%$, standard deviation $=13 \%$, median error $=-0.9 \%$ ). Agency forecasts are, on average, also good predictors of observed returns (average error $=-10 \%$, standard deviation $=$ $40 \%$, median error $=-11 \%$ ). The model's prediction of observed returns, including stocks for which there is no agency forecast, is also good (average error $=-6 \%$, standard deviation $=36 \%$, median error $=-9 \%$ ).

The effect of the error in predicting terminal returns or escapement on the AABM abundance indices varies between fisheries and stocks. There is no clear directional bias of this error. For example, a small stock (small in ocean abundance terms) that is over or under predicted will generally not have a large effect on a fishery's abundance index. Errors in predicting a large stock may or may not affect a fishery's index, depending on the contribution of that stock to the fishery in question (see Appendix I for the model estimated stock composition of selected ocean fisheries). In addition, since the abundance index is an index, rather than an absolute measure of abundance, over or under prediction of a stock's terminal return or escapement would not affect the abundance index of a fishery if the bias in the prediction is consistent over all years in the index, including the base.

Table 3.10. Preseason forecasts and postseason estimates for PSC model stocks, 1999-2005.

## Appendix B. ISBM indices.

## LIST OF APPENDIX B TABLES

## Page

Appendix B.1. ISBM Indices for Canadian fisheries, from both the CWT-based exploitation rate analysis (1999-2003) and the Chinook model (19992005) used to establish the AI for each year. Order of the stock groups correspond to Annex 4, Chapter 3, Attachment IV and V of the PST 1999 Revised Annexes63

Appendix B.2. ISBM Indices for U.S. fisheries, from both the CWT-based
exploitation rate analysis (1999-2003) and the Chinook model (1999
2005) used to establish the AI for each year. Order of the stock groups
correspond to Annex 4, Chapter 3, Attachment IV and V of the PST
1999 Revised Annexes. ..... 64

Appendix B.1. ISBM Indices for Canadian fisheries, from both the CWT-based exploitation rate analysis (1999-2003) and the Chinook model (1999-2005) used to establish the AI for each year. Order of the stock groups correspond to Annex 4, Chapter 3, Attachment IV and V of the PST 1999 Revised Annexes.

The CWT-based estimates, not the model estimates, are to be used in postseason assessments.
${ }^{2}$ NA means not available because of insufficient data (lack of stock specific tag codes, base period CWT recoveries, etc)
${ }^{3}$ Stock or stock group with an agreed CTC escapement goal.
${ }^{4}$ Stock group not in Annex Attachment IV
${ }^{5}$ Indices for this stock are calculated from CWT recoveries for Cowichan; differences between Nanaimo and Cowichan stock indices are due to differences in terminal harvest
${ }^{6}$ An inconsistency was discovered between the approaches used to calculate the model-based and CWT-based indices. The former included harvest rates for terminal sport while the latter did not. Terminal sport harvest rates are now included in the calculation of both indices. Further review is yet required to determine whether the base period terminal sport harvest rates obtained from analyses of Big Qualicum CWT recoveries adequately represent impacts that would have occurred on Cowichan Chinook.
Several problems have been identified in the approach previously used to calculate the CWT-based indices for Nanaimo Chinook; indices for this stock will not be reported as their utility is questionable.
${ }^{8}$ Although model-based indices were previously calculated separately for Cowichan and Nanaimo Chinook, these did not adequately represent impacts on either LGS stock. This is because the model-based data represent an aggregate of the two stocks and methods do not currently exist to correctly disaggregate these data for calculation of the ISBM values. Until such methods are developed, a single index value only will be reported representing the aggregate.
${ }^{9}$ The terminal sport harvest rates for Chilliwack Hatchery Chinook, the indicator stock, were removed from the calculation for the Harrison River naturals this year because sport harvest has been essentially zero on the natural population.
 harvest rates are now included in the calculation of both indices. A further review of the indices for WCVI Chinook will be done to determine whether they represent impacts on the WCVI wild aggregate.
${ }^{11}$ For the Canadian ISBM fisheries, both Lake Washington and Green are assumed to have the same distribution and thus the same index value.

Appendix B.2. ISBM Indices for U.S. fisheries, from both the CWT-based exploitation rate analysis (1999-2003) and the Chinook model (19992005) used to establish the AI for each year. Order of the stock groups correspond to Annex 4, Chapter 3, Attachment IV and V of the PST 1999 Revised Annexes.

## Southeast Alaska Stocks

The PSC CTC Model is used to internally forecast abundance of southern Southeast Alaska hatchery stocks and the aggregate of six wild stocks in the SSEAK Model Stock, which are Andrew Creek and the King Salmon, Unuk, Chickamin, Blossom and Keta Rivers.

## Canadian Stocks

West Coast Vancouver Island

The abundance forecast for the West Coast Vancouver Island (WCVI) model stock is based on the Robertson Hatchery (RBH)/Somass River forecast and the relative run size of other WCVI Chinook populations in the past year. The method used to forecast the terminal run of RBH/Somass Chinook is documented annually in the Canadian Stock Assessment Secretariat (CSAC) Research Documents (www.dfo-mpo.gc.ca/sci/csac/) and has previously been reviewed by a working group of the CTC (March 26, 1996 Interim Report of CTC Workgroup, on file with PSC).

RBH/Somass Forecast: Predictions of ocean abundance for RBH fall Chinook were developed from the CWT data used for the exploitation rate analyses. Sibling regression models were developed using estimated (observed recovery expanded by the catch/sample ratio) CWT recoveries in the fisheries and spawning escapement. The independent variable in these regression models may be the terminal run size at age, or the total production at age (ocean fishing mortality plus terminal run), but the dependent variable in both models is the pre-fishery ocean abundance in the next age class. The terminal run used in these regressions includes the catch of RBH and Somass River Chinook in the Barkley Sound sport fishery, terminal commercial and native gillnet fisheries, and spawning escapement to the Somass system. These regression models only account for production associated with the CWT groups selected to represent RBH brood years.

To account for the total production of RBH and natural Somass production, a ratio is calculated of total terminal return of all hatchery and wild Chinook salmon (by age and brood year) divided by the terminal return of Chinook salmon by age and brood year for the specified CWT groups. Due to the multiple age classes in Chinook salmon, ratios are based on observations in the previous year within the same cohort. For example, the expansion for the age- 4 cohort in 2005 would be expanded by the ratio of age- 3 Chinook salmon observed in 2004 and the age- 2 Chinook salmon observed in 2003. Note that this expansion assumes natural production from the Stamp River exhibits similar behavior and encounters similar fishing pressure as the hatchery stock.

The estimates of age-specific ocean abundance for RBH/Somass Chinook are input to a spreadsheet model used to predict the terminal run size. Terminal runs at age, expected in the next year, are predicted based on changes in ocean exploitation rates (i.e., management scalars) and maturation rates at age. Over the past nine years of extensive changes in ocean and terminal fisheries, this spreadsheet model has predicted the observed terminal run with a mean absolute percent error of $32 \%$ (Figure D1). Error rates were less than half of this value in the past when survival of RBH Chinook was greater and more data were available from fisheries.

Figure D1. Estimated \% annual error [(Expected return - Observed return)/Observed Return] for Prod2, Prod3, and average forecast models when applied to estimating the terminal run size of Stamp Chinook into Barkley Sound in 1988 - 2004, based on a leave-one-out retrospective assessment of the regression models and fishery-specific exploitation rate analyses from the cohort analysis. The mean absolute percent error (MAPE) is also shown.

Annual Error in Terminal Run Size Forecast

Based on the age-structured terminal run to as many as 25 indicator streams, the forecasted terminal run of RBH/Somass Chinook is expanded to account for other WCVI Chinook populations. For example, the 2005 forecast of RBH/Somass was expanded as follows:

| Age <br> Class | RBH/Somass <br> Forecast $^{1}$ | WCVI <br> Expansion <br> Factor | Total <br> WCVI <br> Forecast | Comments |
| :---: | :---: | :---: | :---: | :--- |
| Age 3 | 20,825 | 2.2 | 45,261 | Average expansion of past age-3 returns |
| Age 4 | 85,255 | 1.6 | 135,425 | Age-4 expansion based on observed expansion <br> for age-3 returns in the brood year |
| Age 5 | 16,246 | 2.4 | 38,154 | Expansion based on average value of age-3 and <br> age-4 returns within brood year |
| Total | 122,326 |  | 218,840 | RBH/Somass = 56\% of Total |

1The forecast used in calibration of the CTC model uses base period exploitation rates (i.e., management scalars $=$ $1.0)$.

The age-structured total WCVI forecast is used in the CTC model calibration process.

The abundance forecast for Fraser Late Chinook (FRL in the Chinook Coastwide Model) consists of age-structured forecasts for two separate systems, the Harrison and Chilliwack Rivers, which are summed to project a total spawning escapement of lower Fraser River fall white Chinook. The Harrison River spawning population, estimated annually since 1984 through a mark-recapture program, is large (averaging approximately 110,000 age $3+$ spawners from 1984-2004) and is essentially natural. The Chehalis River Hatchery, located near the confluence of the Chehalis and Harrison Rivers, has released coded-wire tagged (CWT) juveniles originating from adults captured from the Harrison River each year since 1982. Recoveries of adults with CWTs in the Harrison River are so few, however, that this component in the fall white spawning population of Chinook salmon is neither estimated nor considered in the Harrison River forecast. The Chilliwack River spawning population was originally founded from Harrison River brood stock. It has increased substantially since adults began returning to the Chilliwack River and Hatchery in 1983 and now includes a component returning directly to the hatchery as well as a large number of natural spawners (averaging approximately 64,000 age $3+$ spawners from 1997-2004). Both components are enumerated annually and included in the Chilliwack River forecast. Juveniles with CWTs have been released from Chilliwack Hatchery into the Chilliwack River (entering on the south side of the Fraser River, the opposite side of entry of the Harrison River) every year since 1981 enabling this population to be used as an exploitation rate indicator for the Harrison River natural population.

The foundation for the two forecasts is an estimate of the terminal run to each river system. The combination of two distinguishing characters of Fraser Late Chinook (late return timing and white flesh color) make it possible to estimate a total terminal catch from the Area 29 Fraser River commercial and test gillnet fisheries, the lower Fraser River sport and native food and ceremonial fisheries, and the in-river sport fisheries. These catches are apportioned to the Harrison and Chilliwack River populations by using information from estimated Chilliwack CWT recoveries where possible, or by using the proportion of each in the total estimated escapement. Separate programs provide independent estimates of the spawning populations and these are added to each terminal catch estimate to derive terminal run estimates by age class. Terminal fisheries for Fraser Late Chinook are generally small, although the Chilliwack River sport fishery has grown considerably in recent years, and are usually only a modest component of the terminal runs.

The CWT recoveries for Chilliwack Hatchery fall whites are used in a cohort analysis to obtain exploitation rates, maturation rates, and adult equivalent factors by age and brood year. Recovery data even from the most recent fishing year are included. Output data from the cohort analysis are then used in linear sibling regression models to estimate ocean abundance at age for both the Chilliwack and Harrison River populations. The strongest regression models for the Harrison River Chinook are based on the terminal run at one age against the ocean cohort abundance of the following age. For Chilliwack River Chinook, the strongest sibling regression models result from the ocean cohort abundance at one age regressed against that of the following one or more ages. The weaker relationships involving terminal run sizes may be due to uncertainties in the estimation of the escapements of the large, natural spawning component.

The estimates of age-specific ocean abundance for Chilliwack and Harrison Chinook are combined in a spreadsheet model analogous to that previously developed for the Robertson Creek fall Chinook salmon stock (RBH in the Chinook Model). Terminal runs at age are then predicted based on changes in ocean exploitation rates and maturation rates at age. One notable difference from the RBH model, however, is that only the terminal run vs. ocean production spreadsheet models are applicable to the FRL forecasts since catch and CWT data will not be available from the past year's fisheries in Washington State. Consequently, the regression models include only brood years with complete recovery data and the independent variable (terminal run at age) is limited to returns within the Fraser River. These latter data are available within the time required for annual forecasts.

A persistent problem observed with the Fraser Late forecast is significant under-estimation of the Chilliwack terminal runs. The source of this bias has not yet been identified but it has been estimated using a retrospective 'leave-one-out' analysis (Figure D2). The recent 5-year average percent error in the forecast for Chilliwack River (e.g., $-52 \%$ for years 2000-04) is used to adjust the estimated annual ocean abundance in order to derive the terminal run forecast.

Figure D2. Estimated \% annual error [(Expected return - Observed return)/Observed Return] in Chilliwack and Harrison River Chinook forecasts based on a leave-one-out retrospective assessment of the regression models and fishery-specific exploitation rate analyses from the cohort analysis. The 'Combined' bars are the error estimates for the sum of the Chilliwack and Harrison population-specific forecasts. MAPE is the mean absolute percent error.

Annual Error in Terminal Run Size Forecast

## Puget Sound and Strait of Juan de Fuca Stocks

Methodologies for pre-season forecasts are described in joint WDFW-Tribal annual Puget Sound management reports, which are available for Puget Sound management units since 1993.

Hoko River
The forecast for the natural summer-fall Chinook is based on a four-year average of past terminal returns. For 2005, the prediction is 955 Chinook salmon, based on an average of the 2001-2004 returns.

## Elwha River

The hatchery and natural summer-fall Chinook run is forecast using a four-year average of the hatchery and natural terminal returns. The terminal run is defined as the hatchery and natural escapement plus the harvest in the river fishery. In 2005, the forecast based on the average of 2001-2004 is 2,603 fish, which includes hatchery origin and natural origin adults.

## Dungeness River

The spring and summer natural Chinook are aggregated in the forecast as information are inadequate to separate the two stocks. The forecast is based on a four-year average of the terminal (WA Area 6D) runs and is estimated at 685 Chinook salmon for 2005. Recent returns are influenced by the Chinook supplementation program, which, in 2003 comprised of about $81 \%$ of the total return. The spawning success of the hatchery-origin fish is unknown, so its influence on natural production potential is also uncertain and caution is urged when using this forecast,

## Nooksack River

## North Fork Spring Chinook.

For the returns of wild natural origin the forecast is based on the average cohort return rates of the 1995-2004 escapements and is 570 fish for 2005. For the returns from supplementation releases, the average cohort return rates of the 1995-2004 escapements is applied to the acclimation pond release numbers and the prediction for 2005 is 2,063 Chinook. For hatchery releases the average of 1995-2002 age class return rates is applied to the appropriate brood year releases and for 2005 the prediction is 5,054 hatchery fish.

## South Fork spring Chinook.

The number of age four recruits per spawner averaged over the years 1988 to 2003. For the 2005 return the prediction is 289 fish.

## Nooksack/Samish

The average of the recruit per spawner for the last two brood years is used for the forecast of hatchery summer-fall Chinook. This average is applied to both fingerling and yearling releases from all release sites (Samish Hatchery, Slater Slough, Lummi Sea Ponds and Maritime Heritage Center). For 2005, the prediction is 19,523 fish.

The average of the adult returns from 1998-2004 is used for the forecast of hatchery summer-fall Chinook. For 2005, the Washington Area 4B prediction is 380 fish.

## Skagit River

## Spring Chinook (wild).

A single estimate is made for all three populations of spring Chinook returning to the Skagit River. The forecast is based on age-specific return rates per spawner averaged over the return years from 1990-2004. For each age the return rate estimate is applied to the appropriate brood year escapement. This provides a 2005 prediction of 1,905 fish.

## Spring Chinook (hatchery).

Yearling and fingerling forecasts were calculated from the BYs 1985-1999 average brood year return rate by age multiplied by the BY releases of yearlings and fingerlings. The 2005 forecast for hatchery Chinook is 1,804 total adults ( 1,180 fish from fingerling releases and 624 fish from yearling releases).

## Summer/Fall Chinook (Wild).

Natural summer/fall Chinook are forecasted as a management unit using brood-specific data from 1987-2002. Scale data were used to determine age composition from each return year and to calculate the average return rates for each age class. This provided a forecast of 22,989 fish for 2005, which was expanded to an Washington Area 4B estimate using the average ratio of the Washington 4B/terminal run sizes (1.0188) to give a total forecast of 23,421 Chinook salmon.

## Summer Chinook Indicator Stock.

The forecast is generated by multiplying the return/smolt (averaged over brood years 1994-1999) by the appropriate summer Chinook wild indicator stock smolt releases. For 2005 this gives an estimated terminal run size of 547 fish. Using the average ratio of the Area 4B/terminal run sizes (1.0188) the Area 4B forecast is 557 fish.

## Fall Chinook Indicator Stock.

The fall Chinook salmon program obtains brood stock from the river and transports them to Marblemount Hatchery for spawning, incubating and rearing. Since this program is relatively new, specific return data are still incomplete. The first complete BY was in 2004. Forecasting is done by using the 2003 and 2004 return age composition (considered preliminary) and the average return per smolt from BY 1999 and 2000 to forecast the 2005 return, which is estimated at 94 fish for the Washington Area 4B run size.

Stillaguamish River
The natural summer and fall Chinook are estimated as a single unit. The natural production forecast uses recruits per spawner estimated from the brood year 1986 through 1993 using the Stillaguamish North Fork tag data. Since there is evidence of density-dependence in the North Fork population, only those years with escapements of greater than 800 were included in the average recruit per spawner. The average return per spawner is applied to brood years 2000
through 2003 natural escapement for each age cohort adjusted by the geometric mean of estimated marine survival and freshwater indices, assuming zero fishing within all waters. For 2005 the prediction for natural fish is 2,013 Chinook. For the hatchery origin releases, the release numbers are multiplied by the 1993-1997 average survival rate for tagged fish from this program, giving a total of 1,540 hatchery fish predicted for 2005.

Tulalip Hatchery
For these summer-fall hatchery releases the cohort specific release numbers for brood years 1999 through 2003 are multiplied by survival rates from CWTs released in brood years 1986-1991, adjusted by the estimated AEQ rates. The prediction for 2005 is 9,172 fish.

## Snohomish River

For the Wallace River Hatchery yearling releases the average survival rate of BY 1996 and 1997 yearling tag groups is estimated to be $1.0 \%$, which was applied to the annual releases to estimate brood year forecasts. For the subyearling forecast, there are no recent useable CWT groups to provide direct survival estimates, so the Tulalip Hatchery survival estimates of $0.52 \%$ were used as a surrogate. Total forecast for both yearlings and fingerlings is estimated to be 9,934 fish.

The Snohomish wild summer-fall Chinook forecasts use an average recruit per spawner from the Puget Sound Technical Recovery Team's (TRT) Abundance and Productivity tables. This information is available for each of the two component populations (Skykomish and Snoqualmie). But the high average return per spawner (R/S) of 3.21 for the Snoqualmie is suspect, given the variation of visibility conditions during escapement surveys, so the average Skykomish R/S value of 1.81 is used to forecast both the Skykomish and Snoqualmie populations. The natural spawners do include some hatchery-origin fish, so the effective number of spawners is estimated based on both natural-origin and hatchery-origin fish.

Lake Washington

## Cedar River Summer/fall Chinook (natural).

The forecast was generated by applying the four-year average Washington Area 4B run size for a prediction of 593 fish. No attempt was made to breakout HORs versus NORs. There are now three years of smolt data for the Cedar River. The average return is about 0.03 , which would provide an estimate of 1,167 fish, using the 2002 smolt estimate of 39,100 . This may be an alternative forecast method in the future.

North Tributary Summer/fall Chinook (natural).
The forecast was generated by applying the same method as for Cedar River, using a four-year average Washington Area 4B run size for a prediction of 274.

## Issaquah Hatchery Chinook.

The forecast was made using the 2001 brood hatchery pounds released $(31,084)$ multiplied by the 2000-2003 average (UW + Issaquah) return/pound (0.2862). The prediction for 2005 is 6,904 fish.

University of Washington Hatchery (Portage Bay).
The 2001 brood hatchery pounds released (5,712) were multiplied by the 1999-02 average (UW + Issaquah) return/pound (0.2862) for a 2005 prediction of 1,634 Chinook salmon.

## Green River

## Summer/Fall Chinook (natural spawners).

The 2001 brood year escapement $(7,975)$ was multiplied by average $R / S(1.43)$ from years with escapements (1983, 1984, 1992, 1994, 1999, 2000, 2001, 2002) falling within the range of 5,975 to 9,975 . For 2005 the Washington Area 4B prediction is 11,404 fish.

Soos Creek Hatchery Chinook (fingerlings).
The forecast is based on the average cohort return rate (since 1985) for age 3's (0.0914), age 4's ( 0.1635 ) and age 5 's ( 0.0150 ) multiplied by the pounds released for the appropriate brood years. These releases were $38,117,46,586,44,001$; respectively. The Washington Area 4B prediction for 2005 is 11,767 Chinook, with 82.2 percent of the return marked.

Icy Creek Hatchery Chinook (yearlings).
The forecast is based on the average cohort return rate (since 1985) for age 3's (0.0031), age 4's ( 0.0218 ) and age 5 's ( 0.0042 ) multiplied by the pounds of smolts released, which was 28,888 , $32,079,34,333$; respectively. The 4B prediction for 2005 is 932 fish, with $98 \%$ of the fish marked.

Kitsap Tributaries
Grovers Creek Fall Chinook (hatchery fingerlings).
The recent 15-year average (1982-1997) return per number released for contributing brood years (age $3-0.0031637$, age $4-0.0023411$, age $5-0.0000898$ ), was used to provide 2005 forecasts of $1,286,1572$ and 41 Chinook, respectively. The total 2005 return is predicted at 2,899 fish with a marked component of 1,735 , or $60 \%$ marked.

Gorst Creek Fall Chinook (hatchery fingerlings).
The forecast for Gorst Creek fall Chinook is made using survival estimates by age from Grovers Creek hatchery Chinook tagged groups multiplied times the appropriate brood release. The prediction for 2005 is 9,370 fish.

## Dogfish Creek Chinook (hatchery fingerlings).

The average cohort return rate from Grovers Creek hatchery tag groups was applied to the appropriate brood year releases. The prediction for 2005 is 384 fish.

## Clear Creek Fall Chinook (hatchery fingerlings).

The average cohort return rate from Grovers Creek hatchery tag groups was applied to the appropriate brood year releases. The prediction for 2005 is 127 fish.

## Gorst Creek Fall Chinook (hatchery yearlings).

The average cohort return rate from Grovers Creek hatchery tag groups was applied to the appropriate brood year releases. The prediction for 2005 is 887 fish.

The above stocks combined provide the total Washington Area 10E (Kitsap) forecast for 2005 of 10,769 Chinook salmon.

## White River

The forecast for the natural spring Chinook return to the White River Buckley Trap and for the number of adult Chinook (ages 3-5 years) expected to be passed above White River Mud Mountain Dam in 2005 was 2,379 Chinook salmon. The forecast method uses average sibling ratios (e.g. the mean 2-yr-old/3-yr-old return/spawner ratios for several broods) applied to the appropriate brood return (e.g., age 2 -year to age 3 -year ratio applied to the 2002 brood 2 return to predict the age 3 return). Note that this is a total of naturally produced fish, including acclimation pond origin fish and suspected fall-type fish. There are no tools currently available to separate these run components. The spring Chinook return from White River Hatchery and from Minter Creek releases is estimated using average cohort return rates based on CWT information for brood years 1989-2001, multiplied by the number of released fish for each brood year. The prediction for White River hatchery for 2005 is 673 fish and 506 Chinook salmon are expected from Minter Creek releases.

## Puyallup River

The natural forecast for summer-fall Chinook salmon for 2005 is estimated using the predicted mean return at age calculated for return years 1992-2004. However, given that past forecasts have overestimated actual returns, the 2005 prediction was adjusted by the average difference between forecasts and actual returns from 1999 to 2004. The prediction, based on the traditional method (no adjustment), provides an estimate of 3,445 fish. The average of over-forecasting (143.19\%) was applied, giving a lower estimate of 2,406 fish, which is the 2005 estimate.

The basic information was generated from escapement estimates derived by expanding South Prairie Creek Chinook escapements to the entire basin. Total fall Chinook escapements (19941998) were estimated by expanding South Prairie Creek escapement by the mean 1999-2002 South Prairie Creek/Puyallup escapement ratio (mean of 0.62 with range of 0.57 to 0.72 ). Once the age composition was applied to each brood year, the predicted return at age could be estimated to provide total run size. Historic run sizes had to be scaled since the new method, which was initiated in 2001, cannot be compared to run reconstruction. The Puyallup hatchery fall Chinook forecast used the method developed for the last two years, applying mean return rates by age (based on both number and pounds releases) to appropriate brood releases. Return rates were update with age sampling data acquired through the 2004 return. The prediction for 2005 is 4,361 fish.

## Chambers Creek

The forecast for the summer-fall Chinook hatchery fingerlings was derived by multiplying the release in pounds of fingerlings for the 2001 brood year multiplied by the 1994-2003 mean return/pound released. The forecast for hatchery fingerlings 2005 was 2,059 Chinook salmon.

Basin-specific data for Chamber Creek yearlings are not available so the forecast was made by applying age specific mean return /number and pounds derived from Deschutes yearling CWT
releases (1986-93 brood years) to Chambers Creek yearling release numbers and pounds for the appropriate contributing brood years. Separate forecasts made for pounds and numbers, and the two were averaged to provide a yearling forecast of 1,337 fish.

Nisqually River
The summer-fall natural Chinook salmon return is forecast using the 2001 escapement $(1,079$ Chinook salmon) multiplied by the 1997-2003 mean return per/spawner of 2.82 . The prediction for 2005 is 3,038 fish. For the hatchery production, age specific return rates per fish released were applied to the contributing releases data (numbers of fish released) for return years 19922003. The 2005 forecast is 18,432 fish, including 2 -year-old fish. Without age 2 fish, the expected run size is 15,541 hatchery Chinook.

## McAllister Creek

Releases of summer-fall fingerlings from this facility were discontinued after 2001, so no 3-yearolds are expected. Thus, the estimated returns include only 4 and 5 -year olds, decreasing the traditional forecast by $41 \%$. Estimated returns are based on Deschutes River information from 1986-1993. The forecast is based on the mean return per pound and per number of fingerlings released multiplied by the number released. The two means (return per pound and per number released) are used and the results averaged for the final prediction of 2,169 fish for 2005. Yearling hatchery returns were forecast by applying age specific mean return /number released and pounds derived from Deschutes yearling CWT releases (1986-93 brood years) to McAllister Creek yearling release numbers and pounds for the appropriate contributing brood years. The yearling prediction for 2005 is 154 Chinook salmon.

## Deschutes River

For summer-fall hatchery Chinook, yearling and fingerling releases, age specific mean return per pounds released derived from brood years 1986-93 CWT data was used. These were multiplied times the pounds released from Tumwater Falls for the appropriate contributing broods (2000, 2001 and 2002).

Coulter Creek (Washington Areas 13 D-K)
The summer-fall Chinook salmon forecast is simply the mean of 1998-03 run size (4,482 fish). However, since there were no releases for 2001 through 2003 brood year at Coulter Creek, age 3 and age 4 fish are not expected back to the hatchery. Therefore the forecast was downgraded by excluding these age groups, resulting in a prediction for 2005 of 583 fish.

## Carr Inlet

The forecast for summer-fall hatchery Chinook is the average of two methods, multiplying brood releases by mean return per pound and mean return per number released. The average of the two methods provides the forecast, which is 6,511 fish for 2005.

## Hood Canal

The forecast for Hood Canal summer-fall Chinook salmon (hatchery and natural) is the product of brood 2001 fingerling released (in pounds) from WDFW facilities in 2002, multiplied by the average of post-season estimated terminal return rates (terminal run/fingerling pounds released three years previous) for the last four return years (2001-2004), as these are believed to represent the current survival rates. The resulting terminal area forecast is 30,551 Chinook salmon. The forecast is then apportioned at 27,490 hatchery fish (43.7\% George Adams and 56.3\% Hoodsport Hatchery), 3,061 (10.0\%) natural fish based on Puget Sound run reconstruction-based relative contribution of the individual Hood Canal management units in the 2001-2004 return years. These estimates will be used as inputs to generate ocean recruit forecasts during preseason simulation modeling

## Columbia River Stocks

The Upriver Brights (URB) and Lewis River Wild (LRW) are primarily naturally produced stocks while the Spring Creek Tule (SCH) is a hatchery stock. The Tule stocks generally mature at an earlier age than the bright stocks and do not migrate as far north in the ocean. Minor stocks include Lower River Brights (LRB).

## Cowlitz Spring

The forecast is the sum of predicted tributary mouth returns of the Cowlitz, Kalama, and Lewis river spring Chinook stocks. In turn, each tributary forecast was the aggregate of age-specific linear regressions of historical cohort returns, i.e. age 4 was predicted from age 3 and age 5 was predicted from age 4 . The preliminary forecast for 2005 ocean escapement is 24,800 , compared to the 2004 return of 32,400 .

Willamette Spring
The current year forecast was made from a mix of average age-specific run sizes and agespecific linear regressions of cohort returns. The recent 5 -year average age- 3 run size was used as the age- 3 forecast. The regressions of age 4 on age 3 and age 5 on age 4 were used to forecast age 4 and 5 returns, respectively. The preliminary forecast for 2005 ocean escapement is 116,900 , compared to the 2004 return of 143,700 Chinook salmon.

Columbia River Summer
The current year forecast was based on a relationship between jacks and adult returns at the Columbia River mouth. The preliminary forecast for 2005 ocean escapement is 62,400 , compared to the 2004 return of $65,200^{2}$.

[^5]Cowlitz Fall and Bonneville Tule
The Bonneville Tule and Cowlitz fall stocks comprise the LRH stock. The LRH forecast was from brood cohort regressions by age group. Ocean escapement in 2005 is forecast to be 74,100 LRH adults, less than the 2004 actual return of 108,900 and less than the recent 10-year average of 80,620 . The recent 10 -year LRH forecasts were about $71 \%$ of observed returns with a range between $34 \%$ and $94 \%$. The Bonneville Tule and Cowlitz fall individual forecasts are based on an estimate of their proportion of the forecasted total LRH return and are much less accurate than the composite LRH forecast.

## Spring Creek Hatchery

The forecast was based on the cohort ratio of age 3 to age 2, the regression of age 4 on age $2 \&$ 3 , and the regression of age- 5 on age- 4 . Ocean escapement in 2005 is projected to be 114,100 adults, lower than the 2004 actual return of 175,300 adults but higher than the recent 10 -year average of 82,690 . The recent 10 -year forecasts were about $79 \%$ of observed returns with a range of $45 \%$ to $131 \%$.

## Upriver Brights

The current year forecast was the sum of 22 individual forecasts, i.e. 6 stocks x 4 age groups less two exceptions (Lower River Hatchery (LRH) age 6 and Bonneville Pool Hatchery (SCH) age 6). The six stocks were LRH, LRW, SCH, URB, Bonneville Upriver Brights (BUB), and Pool Upriver Bright (PUB). The four age groups were ages 3, 4, 5, and 6. Both age-specific average cohort ratios and age specific cohort regressions were used in the individual forecasts. The preliminary forecast for 2005 ocean escapement is 353,200 adults, compared to the 2004 run of 367,900 , and the recent 10 -year average of 212,610 . The recent 10 -year forecasts were about $88 \%$ of observed returns with a range of $62 \%$ and $110 \%$.

## Mid-Columbia Brights

The current year forecast for Mid-Columbia Brights (MCB) is the sum of the Bonneville Upriver Bright (BUB) and Pool Upriver Bright (PUB) forecasts. For the BUB component, the age 3 and 4 forecasts were made from brood cohort ratios, and age 5 and 6 from cohort regressions. For the PUB component, the age 3 forecast was made from a recent 5-year average return, and the other age groups from brood cohort regressions. Ocean escapement in 2005 is forecast to be 89,400 MCB adults, less than the 2004 actual return of 117,600 adults but more than the recent 10-year average of 73,100 . The recent 10 -year forecasts were about $90 \%$ of observed returns with a range of $57 \%$ to $128 \%$.

## Lewis River Wild

The forecasts are based on cohort regressions by age group except for age-4, which is based on cohort ratios. Ocean escapement in 2005 is forecast at 20,200 adults, which is slightly less than the 2004 actual return of 22,300 , both an improvement over the recent 10 -year average of 15,260 . The recent 10 -year average forecasts were about $81 \%$ of observed returns with a range of $34 \%$ to $110 \%$.

## Oregon Coastal North Migrating

Forecasts of spawning escapements are made for an aggregate of Chinook salmon populations from seven major river systems on the North Oregon Coast (NOC). River systems in the aggregate include: Nehalem, Tillamook, Nestucca, Siletz, Yaquina, Alsea, and Siuslaw. Annual escapement estimates are made from expansions of fish density indices (peak live + dead fish per mile) observed at standard survey sites in each river basin. These river specific indices are adjusted for observation efficiency and for bias. The abundance for each river is then estimated by multiplying the index by the assumed length of spawning habitat in the river. A three-year-moving-average of escapement is used as the forecast for each river in the forthcoming year. The NOC escapement forecast is the sum of the seven river forecasts. The 2005 forecast is 67,213 Chinook salmon.

${ }^{1}$ Ocean exploitation rates based only on ocean fisheries are shown for stocks in which terminal fisheries differentially impact the coded-wire tagged indicator compared to the associated wild stock. Total exploitation rates based on ocean plus terminal fisheries are shown for stocks in which fishery impacts on the indicator and the associated wild stock are similar in terminal areas. Exploitation rates are not shown for the following hatchery stocks because they are not associated with a wild stock: University of Washington Accelerated, South Puget Sound Fall Yearling, Squaxin Pens Fall Yearling. Exploitation rates cannot be calculated for the following stocks without sufficient escapement data: Nisqually Fall Fingerling, White River Spring Yearling, Elwha Fall Fingerling.
${ }^{2}$ The corresponding stocks used in the Chinook model calibration are indicated in brackets.

Appendix G. Percent distribution of landed catch and total mortality among fisheries and escapement for exploitation rate indicator stocks by calendar year.

These data result from cohort analysis of CWT recoveries for the indicator stocks; data within a row for each calendar year sum to $100 \%$. Some changes are present in these distribution tables compared to those presented in previous reports. There are various reasons for the changes including updates to escapement time series, in the case of some Columbia River stocks. Also, a computational rule used in producing the stock-specific distribution tables determines whether data are reported for any particular calendar year. The rule is that at least three year classes of CWT recoveries (out of four or five) must be available in any calendar year. Lack of CWT releases in recent years for some of the indicators has resulted in no distribution data for 2000-2003. Missing broods are noted in the appropriated tables.

Appendix H. Time series of abundance indices from 1979 to 2005 for SEAK, NBC, and WCVI AABM fisheries as estimated by CTC Chinook Model calibration CLB0506. This time series is NOT the first postseason AI and is for trend analysis only (Figure 3.1, 3.2, and 3.3, Appendix J). For evaluation of overage and underage (Tables 3.3 and 3.4), use the first postseason AI in Table 3.2 instead.

| Year | SEAK | NBC | WCVI |
| :---: | :---: | :---: | :---: |
| 1979 | 0.97 | 1.04 | 1.10 |
| 1980 | 1.03 | 0.98 | 0.97 |
| 1981 | 0.92 | 0.94 | 0.93 |
| 1982 | 1.08 | 1.05 | 1.01 |
| 1983 | 1.28 | 1.23 | 0.93 |

| 2003 | 2.22 | 1.93 | 1.13 |
| 2004 | 2.06 | 1.83 | 0.98 |
| 2005 | 2.05 | 1.69 | 0.88 |

Appendix I. Model estimates of the stock composition of the AABM, and other troll and sport fisheries for 2004 and the average from 1985 to 2003.
"Catch as Percent of Fishery" represents the stock composition of a specific fishery; "Catch as Percent of All Fisheries" represents the proportion of the total catch of a stock that is caught in a specific fishery; "Percent of Total Return" represents the proportion of total return (catch + escapement) caught in a specific fishery.

Table J.2. Abundance indices (AIs) for the Northern BC troll fishery by stock and year (stock groups 1-15) ), from CLB 0506.
Numbers represent the model stock contribution to the total AI: the summation across all 30 stocks and stock groups equals the AI total for each calendar year.

Table J.3. Abundance indices (AIs) for the WCVI troll fishery by stock and year (stock groups 1-15) ), from CLB 0506.
Numbers represent the portion of the AI total estimated for each model stock; the summation across all 30 stock groups equals the AI total for each.

Appendix K. Fishery indices by stock, age and fishery, 1975-2003.

## LIST OF APPENDIX K TABLES

PAGE
Table K.1. Alaska troll Stratified Proportion Fishery Index (SPFI) values as landed catch. ..... 191
Table K.2. Alaska troll Stratified Proportion Fishery Index (SPFI) values as total mortality. ..... 192
Table K.3. Landed catch exploitation rates and exploitation rate indices by stock and age in the NBC troll fishery. Base period is 1979-1982. ..... 193
Table K.4. Total mortality exploitation rates and exploitation rate indices by stock and age in the NBC troll fishery. Base period is 1979-1982. ..... 194
Table K.5. Landed catch exploitation rates and exploitation rate indices by stock and age in the WCVI troll fishery. Base period is 1979-1982. ..... 195
Table K.6. Total mortality exploitation rates and exploitation rate indices by stock and age in the WCVI troll fishery. Base period is 1979-1982 ..... 196

Table K.1. Alaska troll Stratified Proportion Fishery Index (SPFI) values as landed catch.

Appendix M. Incidental mortality rates applied in the CTC model. Rates in original model were applied to all years. In the current model, rates in some fisheries vary in accordance to changes in management regulations.

| Fishery Number | Fishery | Rates in original Model |  |  | Rates applied in Model CLB0506 |  |  |  |

[^0]:    ${ }^{1} 35$ estimated recoveries for a given stock and age combination.

[^1]:    ${ }^{1}$ Separate indices were computed for these stocks prior to 2005 . The CTC identified inconsistencies with this method and chose

[^2]:    $\mathrm{NA}=$ not available

[^3]:    $\mathrm{NA}=$ not available

[^4]:    ${ }^{8 .}$ See the footnote for the corresponding value in the table of indices for the Canadian ISBM fisheries.

[^5]:    ${ }^{2}$ Starting in 2005, the Columbia summer Chinook forecast are for those Chinook passing Bonneville Dam starting on June 15, instead of June 1. Thus in last year's report, the 2004 forecast with the June 1 start date was 102,800. The same forecast with the June 15 start date would have been 69,100 .

[^6]:    No data are shown for 2000-2003 because of lack of coded-wire tagging of broods from 1998-2000
    ${ }^{2}$ Values represent estimates of catch distribution only because escapement is of insufficient quality.
    ${ }^{3}$ Relatively high age-2 survival, combined with relatively few total catch recoveries of CWTs, result in large estimates of sublegal CNR mortality in 1995 and 1999.

[^7]:    No data are shown for 2001 to 2003 because of lack of coded-wire tagging of broods from 1998-2000.
    ${ }^{2}$ Values represent estimates of catch distribution only for this year because escapement data is of insufficient quality.

[^8]:    No data are shown for 2001 to 2003 because of lack of coded-wire tagging of broods from 1998-2000.
    ${ }^{2}$ Values represent estimates of total fishing mortality distribution only for this year because escapement data is of insufficient quality.
