PACIFIC SALMON COMMISSION
JOINT CHINOOK TECHNICAL COMMITTEE REPORT
2010 ANNUAL REPORT OF CATCHES AND ESCAPEMENTS

REPORT TCCHINOOK (11)-2

February 10, 2011

## MEMBERSHIP OF THE CHINOOK TECHNICAL COMMITTEE

Canadian Members
Mr. Chuck Parken, Co-Chair, CDFO
Mr. Richard Bailey, CDFO
Dr. Gayle Brown, CDFO
Ms. Diana Dobson, DFO
Mr. Roger Dunlop, FNC
Ms. Dawn Lewis, CDFO
Ms. Teresa Ryan, FNC
Mr. Julian Sturhahn, CDFO
Dr. Arlene Tompkins, CDFO
Mr. Ivan Winther, CDFO
Mr. Howie Wright, FNC
Dr. Antonio Velez-Espino, DFO

United States Members
Dr. Rishi Sharma, Co-Chair, CRITFC
Mr. John Carlile, Co-Chair, ADF\&G
Dr. Dave Bernard, ADF\&G
Mr. Ryan Briscoe, ADF\&G
Mr. Ethan Clemons, ODFW
Dr. John H. Clark, ADF\&G
Mr. Gary Freitag, UAF
Mr. Ed Jones, ADF\&G
Dr. Robert Kope, NMFS
Mr. Brian Lynch, ADF\&G
Ms. Marianne McClure, CRITFC
Mr. Scott McPherson, ADF\&G
Dr. Gary Morishima, QIN
Mr. James Packer, WDFW
Dr. Ken Warheit, WDFW
Mr. Alex Wertheimer, NMFS
Mr. Henry Yuen, USFWS
Dr. Marianna Alexandersdottir, NWIFC
Dr. Yong-Woo Lee, WDFW
Mr. William Templin, ADF\&G

## LIST OF ACRONYMS WITH DEFINITIONS

| AABM | Aggregate Abundance Based Management | MSF | Mark-Selective Fishery |
| :---: | :---: | :---: | :---: |
| AC | Allowable Catch | MSH | Maximum sustainable harvest |
| AI | Abundance Index | MSY | Maximum Sustainable Yield for a stock, in adult equivalents |
| ADF\&G | Alaska Department of Fish \& Game | MSY ER | Exploitation Rate sustainable at the escapement goal for a stock, in AEQs |
| AEQ | Adult Equivalent | NA | Not Available |
| Agreement | June 30, 1999 PST Annex and the related Agreement | NBC | Northern British Columbia Dixon Entrance to Kitimat including Queen Charlotte Islands |
| AUC | Area Under the Curve | NM | Nautical Mile |
| AWG | Analytical Working Group of the CTC | NMFS | National Marine Fisheries Service |
| BCAFC | British Columbia Aboriginal Fisheries Commission | NOC | Oregon Coastal North Migrating Stocks |
| BTR | Base Terminal Run | NPS | North Puget Sound |
| C\&S | Ceremonial \& Subsistence | NPS-S/F | North Puget Sound Summer/Fall Chinook stock |
| CBC | Central British Columbia Fishing area Kitimat to Cape Caution | NR | Not Representative |
| CCMP | Comprehensive Chinook Management Plan | NWIFC | Northwest Indian Fisheries Commission |
| CDFO | Canadian Department of Fisheries \& Oceans | ODFW | Oregon Department of Fish \& Wildlife |
| CI | Confidence Interval | PFMC | Pacific Fisheries Management Council |
| CNR | Chinook Non-retention | PS | Puget Sound |
| CR | Columbia River | PSC | Pacific Salmon Commission |
| CRITFC | Columbia River Intertribal Fish Commission | PSARC | Pacific Scientific Advice Review Committee |
| CRFMP | Columbia River Fishery Management Plan | PSMFC | Pacific States Marine Fisheries Commission |
| CTC | Chinook Technical Committee | PST | Pacific Salmon Treaty |
| CUS | Columbia Upriver Spring Chinook stock | QDNR | Quinault Department of Natural Resources, Division of fisheries |
| CWT | Coded Wire Tag | QIN | Quinault Nation |
| DIT | Double Index Tag | QCI | Queen Charlotte Islands |
| ESA | U.S. Endangered Species Act | RER | Recovery Exploitation Rate |
| Est+fw | Estuary Plus Fresh Water Area | $\mathrm{S}_{\text {MSY }}$ | Escapement producing MSY |
| FL | Fork Length | SEAK | Southeast Alaska Cape Suckling to Dixon Entrance |
| FMP | PFMC Framework Management Plan | SG | Strait of Georgia |
| FNC | First Nations Caucus | SPS | South Puget Sound |
| FOG | Fisheries Operational Guidelines | SWVI | Southwest Vancouver Island |
| FR | Fraser River | TAC | Technical Advisory Committee |
| GCG | Gene Conservation Group | TBR | Transboundary Rivers |
| GW | Gitwinksihlkw | TTC | Transboundary Technical Committee |
| GS | Strait of Georgia | UAF | University of Alaska Fairbanks |
| HOR | Hatchery Origin Returns | UFR | Upper Fraser River |
| IDFG | Idaho Department of Fish \& Game | UGS | Upper Strait of Georgia |
| IDL | InterDam Loss | USCTC | U.S. members of the CTC |
| IM | Incidental Mortality | USFWS | U.S. Fish \& Wildlife Service |
| ISBM | Individual stock based management | UW | University of Washington |
| LFR | Lower Fraser River | WA/OR | Ocean areas off Washington and Oregon North of Cape Falcon |
| LGS | Lower Strait of Georgia | WAC | Washington Coast (Grays Harbor northward) |
| mar | Marine Area | WACO | Washington, Oregon, Columbia River Chinook stock group |
| mar+fw | Marine Plus Fresh Water Area | WCVI | West Coast Vancouver Island excluding Area 20 |
| MOC | Mid Oregon Coast | WDFW | Washington Department of Fisheries and Wildlife |

## EXECUTIVE SUMMARY

The June 30, 1999, Pacific Salmon Treaty (PST) Annexes and Related Agreements (Agreement) substantially changed the objectives and structure of the Pacific Salmon Commission's (PSC) Chinook salmon fisheries and assessment of Chinook salmon stocks. The 1999 Agreement replaced the previous ceiling and pass-through fisheries with Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries. The 2008 Agreement replaced the 1999 Agreement and assigned the Chinook Technical Committee (CTC) with several tasks related to implementation of the Agreement (Appendix to Annex IV, Chapter $3)$.

This report summarizes the 2009 fishery catches by region, available estimates of incidental mortality by fishery and limited commentary on fishery catches where needed. Landed catch is reported in the appendices for each geographic area covered under the PST. An assessment of escapement for stocks with CTC accepted goals is included, and escapement data through 2009 are provided for all escapement indicator stocks.
The escapements of 50 naturally spawning escapement indicator stocks/stock aggregates are reviewed annually. Biologically-based escapement goals have been accepted by the CTC for 24 of the 50 escapement indicator stocks/stock aggregates. For 12 of these, the escapement goal is defined as a range; for the remaining 12, the escapement goal is the point estimate of $\mathrm{S}_{\text {MSY }}$ (escapement producing maximum sustained yield). In 2009, escapements were within the goal range for 3 stocks, above the range or $\mathrm{S}_{\mathrm{MSY}}$ point estimate for eight stocks, and below the goal for 14 stocks. Data for stocks without accepted goals are presented to illustrate trends in escapement. The CTC will continue to review escapement goals, as they are provided to the committee.

## 1 CHINOOK CATCH

The June 30, 1999, Pacific Salmon Treaty (PST) Annexes and Related Agreements (Agreement) substantially changed the objectives and structure of the Pacific Salmon Commission’s (PSC) Chinook salmon fisheries. The 1999 Agreement eliminated the previous ceiling and pass-through fisheries and replaced them with Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries. The 2008 Agreement defines catch limits for AABM fisheries; and ISBM fisheries are limited by adult equivalent mortality rates. Chinook salmon catches for the AABM fisheries in 2009 are summarized in Table 1.1-Table 1.4. Historical catches for PSC Chinook salmon fisheries are given in Appendices A.1-A.14.
Starting with the report CTC (2004a), the Chinook Technical Committee included estimates of incidental mortalities associated with landed catch for each component of each AABM fishery and most ISBM fisheries (CTC 2004b). Limited commentary on both AABM and ISBM fisheries is also provided.

### 1.1 REVIEW OF AABM FISHERIES

AABM fisheries for Chinook salmon are managed to achieve a target catch corresponding to a target harvest rate index and each year's abundance index (AI) in Table 1 of the Agreement. AABM fisheries are mixed stock salmon fisheries that intercept and harvest migratory Chinook salmon from many stocks. The AABM fisheries (Annex IV, Chapter 3, paragraph 2) are:

1) Southeast Alaska (SEAK) All Gear,
2) Northern BC (NBC) Troll and Queen Charlotte Islands (QCI) sport, and
3) West Coast Vancouver Island (WCVI) Troll and Outside Sport.

Catches for these three fisheries are reported in Table 1.1.

Table 1.1. Annual catches and hatchery add-ons for the AABM fisheries, in thousands of Chinook salmon. The Treaty catches do not include the add-on or exclusions(see Section 1.1.1 and Appendix A.1). Notation is T for Troll, N for Net and S for sport.

| Year | SEAK (T, N, S) |  |  | $\begin{gathered} \text { NBC (T), QCI (S) } \\ \hline \text { Treaty Catch } \end{gathered}$ |  | WCVI (T, S) <br> Treaty Catch |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2007 | 329.4 | $328.4^{3}$ | $69.6^{3}$ | 143.0 | 144.2 | 121.9 | 139.2 |
| 2008 | 152.9 | $172.3^{3}$ | $68.2^{3}$ | 120.9 | 95.6 | 136.9 | 143.8 |
| $2009^{4}$ | 176.0 | 229.5 | 65.2 | 139.1 | 109.5 | 91.3 | 124.6 |
| 2010 | 221.8 |  |  | 152.1 |  | 143.7 |  |

${ }^{1}$ Allowable treaty catches correspond to the postseason AIs for 1999-2009 and the preseason AI for 2010.
${ }^{2}$ Values reverted back to original values published in TCCHINOOK05-2.
${ }^{3}$ Values changed due to correction in the accounting of the TBR terminal exclusion.
${ }^{4} 2009$ was the beginning of the 2008 Agreement

### 1.1.1 Southeast Alaska Fisheries

The SEAK Chinook salmon fishery has been managed to achieve the annual all-gear PSC allowable catch through a plan established by the Alaska Board of Fisheries. Once the all-gear allowable catch is determined from the preseason AI each spring, this plan establishes gear quotas for the troll, net, and sport fisheries. The allocation plan reserves $4.3 \%$ of the total PSC catch for purse seine, $2.9 \%$ for drift gillnet and 1,000 fish for set gillnet fisheries. After the net quotas are subtracted, $80 \%$ of the remainder is reserved for troll gear and $20 \%$ for the sport fishery. The sport fishery is managed in-season with bag-limits and other constraints. Regulatory history and maps for each SEAK fishery are detailed in CTC (2004b).
In addition, the SEAK fisheries were managed for:

1) An Alaskan hatchery add-on estimated from CWT sampling. The add-on is the total estimated Alaskan hatchery harvest, minus 5,000 base-period Alaskan hatchery harvest, and minus one-half of the $90 \%$ confidence interval for the total Alaskan hatchery harvest.
2) An exclusion of wild Chinook salmon originating from the Stikine and Taku River.
3) Compliance with provisions established by the National Marine Fisheries Service in accordance with the U.S. Endangered Species Act (ESA).
4) Consistency with the provisions of the PST as required by the Salmon Fishery Management Plan of the North Pacific Fishery Management Council that was established by the U.S. Magnuson-Stevens Act.

The 2009 pre-season AI of 1.33 allowed an all-gear catch of 218,800 fish. The all gear harvest was 299,346, comprised of a Treaty catch of 229,509, an add-on of 65,179 , and terminal exclusion catch of 4,658 Chinook salmon. A breakdown by gear for total catch, Alaskan hatchery contributions and terminal exclusions is detailed in Table 1.2. Historical harvests for 1975-2009 for SEAK are in Appendix A.1.

### 1.1.1.1 Troll Fisheries Harvest

Troll fishery regulations in 2009 were similar to those in 2008. The accounting year began with the start of the winter fishery on October 11, 2008 and ended the following September, 2009. The winter fishery continues until 45,000 Chinook salmon are caught or through April 30, whichever is earlier. In 2009, the harvest in the winter fishery was less than 45,000 and the winter troll fishery was closed on April 30. The spring fisheries were managed so that each fishery would not exceed a predetermined number of non-Alaskan Chinook salmon based on the Alaskan hatchery percentage in each of the small fisheries. The first summer fishery opening began on July 1 and was managed to harvest $70 \%$ of the remaining troll gear Chinook salmon quota based on the pre-season AI. After the first $70 \%$ of the summer quota was harvested, the troll fishery was closed to Chinook salmon retention and the areas of high Chinook abundance were closed while the fishery was directed primarily onto coho salmon (in recent years, a large portion of the troll fleet has also targeted on chum salmon). No in-season adjustment of the AI was made because the results using the methodology established by the CTC and used since 1997 were poorly correlated with the first post-season calibration. A second summer Chinook salmon retention period began in August to catch the remaining 30\% of the summer quota.. The areas of high Chinook salmon abundance remained closed during this second summer Chinook retention period.

In 2009, the troll fishery harvested 175,644 Chinook salmon, including 20,522 Alaskan hatchery fish. Subtracting an Alaska hatchery add-on of 16,602 results in a treaty catch of 159,042 (Table 1.2). The winter fishery harvested 24,889 of which 2,756 were from Alaskan hatcheries, with a total of 22,664 treaty fish. The spring fishery harvested a total of 32,859 of which 12,542 were Alaskan hatchery fish and 22,699 were treaty fish. The total summer harvest was 117,896 of which 5,224 were from Alaskan hatcheries and 113,679 were treaty fish.

### 1.1.1.2 Net Fisheries Harvest

Net harvest of Chinook salmon in the purse seine fishery is limited by a 28 " ( 71 cm ) minimum size limit and the use of Chinook salmon non-retention (CNR) regulations. Chinook salmon between 21" and 28 " may never be sold, while Chinook salmon below 21 " may be retained at all times. Gillnet harvest of Chinook salmon is limited by a delayed season opening in late June
unless directed fisheries are implemented for stocks of Chinook salmon bound for the Taku and Stikine Rivers. Directed fisheries were in place in 2009 for Taku River Chinook salmon, but did not occur for Stikine River Chinook salmon in 2009.

The 2009 total net harvest was 54,137 Chinook salmon (Table 1.2). There was a total of 4,658 fish excluded from the gillnet harvest and 28,781 Chinook salmon were from Alaskan hatcheries. The total net treaty harvest was 22,378 Chinook salmon. The treaty harvest by gear type was 1,533 for set gillnet, 7,254 for drift gillnet and 13,591 for purse seine.

### 1.1.1.3 Recreational Fishery Harvest

In 2009, the recreational fishery had a two fish daily bag limit for all residents. Non-resident anglers had a one fish daily and a three fish annual limit. The minimum size limit of 28 " in total length was in effect for both resident and non-resident anglers throughout the season. In "terminal" areas near hatchery release sites, however, bag and size limit regulations were liberalized to provide for increased harvests of returning Alaskan hatchery Chinook salmon. Preliminary recreational harvests are estimated in-season by creel surveys throughout the region, and final harvest numbers are estimated one year later using results from the mail out Statewide Harvest Survey (SWHS). Sampling programs are in place to recover coded-wire tagged Chinook salmon. The Alaska hatchery contribution is determined from the CWT sampling program. The final total harvest in 2009 was 69,565 Chinook salmon with 24,988 being Alaskan hatchery fish (Table 1.2). The total sport harvest of 69,565 minus the 21,476 hatchery add-on resulted in a treaty harvest of 48,089 Chinook salmon.
Table 1.2. Harvest of Chinook salmon in SEAK by gear type in 2009.

| Gear | Total <br> Harvest | Alaskan <br> Hatchery <br> Harvest | Alaskan <br> Hatchery <br> Add-on | Catch <br> Exclusion ${ }^{1}$ | Treaty Catch |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Troll |  |  |  |  |  |
| Winter | 24,889 | 2,756 | 2,225 | 0 | 22,664 |
| Spring | 32,859 | 12,542 | 10,160 | 0 | 22,699 |
| Summer | 117,896 | 5,224 | 4,217 | 0 | 113,679 |
| Troll subtotal | 175,644 | 20,522 | 16,602 | 0 | 159,042 |
|  |  |  |  |  |  |
| Sport | 69,565 | 24,988 | 21,476 | 0 | 48,089 |
|  |  |  |  |  |  |
| Net |  |  |  |  |  |
| Set Net | 1,533 | 0 | 0 | 0 | 1,533 |
| Driftnet | 23,592 | 12,808 | 11,680 | 4,658 | 7,254 |
| Seine | 29,012 | 15,973 | 15,421 | 0 | 13,591 |
| Net subtotal | 54,137 | 28,781 | 27,101 | 4,658 | 22,378 |
|  |  |  |  |  |  |
| Total | 299,346 | 74,291 | 65,179 | 4,658 | 229,509 |

${ }^{1}$ Exclusion catch is a result of the harvest sharing arrangement on the Taku and Stikine Rivers.

### 1.1.2 British Columbia Fisheries

Under the 1999 PST Agreement, aggregate abundance based management regimes ("AABM") were implemented to constrain catch. This agreement extended through 2008 and was renewed in the 2009 PST Agreement to 2018. The NBC AABM fishery was defined to include NBC troll catch in Statistical Areas 1-5 and QCI sport catch in Statistical Areas 1 and 2. The total NBC AABM catch in 2009 was 109,470. The WCVI AABM fishery includes the WCVI troll and a portion of the WCVI Chinook salmon sport fishery (defined below). The total WCVI AABM landed catch in 2009 was 124,617 (Table 1.3). Troll catches from 1996-2004 have been updated with data from the Catch Finalization Project.

### 1.1.2.1 NBC Troll Fishery Harvest

The NBC troll fishery landed 75,470 Chinook salmon in 2009. The North Coast B.C. troll fishery was opened for Chinook salmon fishing from 15 June to 3 August and from 22 August to 30 September. The entire 2009 NBC Troll fishery was conducted under a system of individual transferable quotas. A total of 284 vessels were licensed for the NBC Troll fishery. All licences were activated but the harvest was conducted by a total of 147 vessels as much of the quota was transferred. Barbless hooks and revival boxes were mandatory in the troll fishery and the minimum size limit was 67 cm . No troll test fisheries were conducted in the North Coast of B.C. in 2009. A ribbon boundary around Langara Island and from Skonun Point to Cape Knox on Graham Island excluded the commercial troll fishery from areas within one nautical mile of the shore up to 14 September when the restriction was removed.
Table 1.3 Summary of landed catch by gear for Canadian AABM fisheries in 2009.

| AABM Fishery | Troll | Sport | Total |
| :--- | :---: | :---: | :---: |
| NBC | 75,470 | 34,000 | 109,470 |
| WCVI | 58,191 | 66,426 | 124,617 |

### 1.1.2.2 NBC and CBC Sport Fishery Harvest

Tidal recreational fisheries in NBC and CBC (marine Statistical Areas 1-11) are managed under one set of regulations ( 45 cm minimum size limit; two Chinook per day and four in possession; annual bag limit of 30). During the decade up to 2008, recreational fisheries in the marine areas of NBC and CBC expanded substantially. Management of these marine recreational fisheries now recognizes two regions: QCI, and the coastal mainland. Only the QCI recreational catch is included in the AABM totals. Since 1995, catches in the QCI recreational fisheries have been estimated by creel surveys, lodge logbook programs and independent observations by CDFO staff. Catch for this fishery in 2009 was 34,000 Chinook salmon. The total NBC AABM catch (troll plus sport) between October 1, 2008 and September 30, 2009 was 109,470 Chinook salmon (Table 1.3).

### 1.1.2.3 West Coast Vancouver Island AABM

Under the 2008 PST Agreement, the WCVI AABM fishery includes the WCVI troll and the outside WCVI sport fishery (defined below). The total AABM landed catch (First Nations troll, commercial troll, and outside tidal sport) in 2009 was 124,617 Chinook salmon (Table 1.3).

### 1.1.2.3.1 WCVI Troll Fishery Harvest

The AABM troll catch includes the commercial and First Nations troll caught Chinook salmon in Statistical Areas 21, 23-27, and 121-127. In the 2009 season (October 1, 2007-September 30, 2008), the WCVI troll fishing opportunities were consistent with a CDFO commitment to evaluate winter fisheries as a means to improve the economic base for the fleet and local communities while increasing flexibility in harvest opportunities and reducing the harvest rates on stocks encountered in summer fisheries (Table 1.4). Troll fishery openings were shaped by conservation concerns for Fraser River Spring Run Age 1.2 and Fraser River Spring Run Age 1.3, WCVI and Lower Strait of Georgia (LGS) Chinook salmon and interior Fraser River Coho salmon.

To reduce impacts on early spring-run Fraser and LGS Chinook salmon, SWVI areas 123-124 were closed from mid-March to mid-April. To reduce impacts on interior Coho, Coho nonretention remained in effect for the spring/summer period, Fraser Coho encounter rates were monitored, and commercial fisheries were closed from late June until late July. To reduce impacts on WCVI Chinook salmon, summer fisheries were limited to 10,000 Chinook salmon, and the July to September fisheries were conducted 5 nautical miles seaward of the surfline. To reduce impacts on LGS Chinook salmon, harvest levels were reduced during the spring period when recent impacts were highest (by reducing the TAC by 20\%). The April catch was reduced from 57,063 in 2005 to 3,616 in 2009. May Chinook salmon catch in 2009 was 18,062 and within the 2005-2006 range ( 26,655 in 2005; 7,078 in 2006). This measure also provides some benefits to spring run US Chinook salmon stocks when the mature run is abundant on the WCVI. Statistical Area 121 (the southern bank area) remained closed in 2009. Selective fishing practices were mandatory, including single barbless hooks and "revival tanks" for resuscitating Coho salmon prior to release. The minimum size limits for commercial troll for all periods was 55 cm (fork length). The majority of catch from November through March came from Area 126.

The catches for 2009 commercial troll fisheries between October 1, 2008 and September 30, 2009 were 53,191 Chinook salmon (Table 1.4). WCVI First Nations caught an estimated 5,000 Chinook salmon in 2009. Therefore, the total WCVI AABM troll catch for 2009 was 58,191 with 345 legal and 4,117 sublegal Chinook salmon releases (not including releases from the WCVI First Nations troll fisheries, which are currently unknown).

Table 1.4 Fishing periods and Chinook salmon harvested and released during the 2009 accounting year in the WCVI commercial troll fishery.

Note: WCVI troll fisheries were generally closed from mid June to late August to avoid encounters of interior Fraser River and Thompson River Coho and WCVI Chinook salmon.
${ }^{1}$ DNA sampling of sublegal Chinook salmon by Area G.

### 1.1.2.3.2 WCVI Recreational Fishery Harvest

The AABM recreational fishery includes all catch in northwest WCVI (Areas 25-27, 125-127; Figure 1) between October 16 through June 30, and the catch outside of one NM offshore from July 1 through October 15, plus all the catch in southwest WCVI (Areas 21-24) between October

16 through July 31, and outside one NM offshore from August 1 to October 15. Catch inside the surf line and outside the AABM periods specified above is included in ISBM fishery catch.

The outer WCVI sport fishery occurs primarily in the Barkley Sound, outer Clayoquot Sound, and Nootka Sound areas. The majority of fishing effort occurs from mid-July to September in NWVI and August through mid-September in the SWVI. Creel surveys were conducted from early June to mid September. For the outside sport fishery the Chinook salmon daily bag limit was two Chinook salmon greater than 45 cm . Barbless hooks were mandatory.

The 2009 WCVI AABM sport catch estimate during the creel period was 66,426 Chinook salmon (Table 1.5). Catch rates were determined from anglers interviewed June 1 to September 15. No creel surveys occurred between the months of October and May, when effort is relatively low.

Table 1.5 Outer WCVI AABM sport fishery catches of Chinook salmon by Pacific Fishery Management Areas in 2009 representing catch from June 1 to September 15 only.

### 1.2 ESTIMATES OF INCIDENTAL MORTALITIES IN AABM FISHERIES

### 1.2.1 SEAK Fisheries

Estimates of encounters and incidental mortality (IM) in SEAK fisheries are shown in Table 1.6. Estimates were converted from landed catch into treaty catch by multiplying the landed catch estimate of encounters by the ratio of treaty catch to landed catch for each respective fishery. The 2009 troll encounters were estimated from regressions of historical encounter estimates and troll effort. The regression predicts encounter estimates from troll effort using encounter estimates obtained from direct fishery observation programs conducted during a series of years. The retention and CNR sublegal regressions use a data series from 1998-2006, while the CNR legal regression uses a data series from 1985-1988 and 1998-2006. Sport fishery survey data from 2009 has not been tabulated, but 2008 sport fishery encounters were updated from the number of Chinook salmon caught and released as recorded on the annual Statewide Harvest Survey (mailin survey) forms. Legal and sublegal CNR purse seine encounters were calculated using a modified catch per landing approach that uses the relationship between the yearly catch and the magnitudes of legal and sublegal CNR encounters for years where we have direct observational data. For the gillnet fishery, drop-off mortality was estimated as a percentage of the landed catch using the regional-specific drop-off rate for SEAK (CTC 2004c). Encounter estimates are multiplied by the respective IM rate found in CTC (1997) to obtain estimates of IM.

Table 1.6 Estimated treaty encounters and treaty incidental mortality in SEAK troll, net and sport fisheries for 2002-2009. Mortality estimates of fish released in troll and sport fisheries include drop-off mortality. In the net fishery, 21 "-28" fish from both retention and non-retention periods are included in the CNR numbers.

### 1.2.2 British Columbia Fisheries

### 1.2.2.1 NBC Fisheries

Table 1.7 summarizes encounter and IM estimates for the NBC AABM fisheries from 2002 to 2009 by size class during retention and Chinook salmon Non-retention (CNR) fishing periods. Encounters for the NBC troll fishery are based on phone-in hails. Encounters for the QCI sport fishery are based on creel survey and logbook programs. The table presents IM estimates using size specific rates from the CTC (1997). The estimated total mortality of Chinook salmon in the NBC AABM fisheries in 2009 was 119,280 nominal fish, including 109,470 fish in the landed catch and 9,810 fish from IM (Table 1.7).

Table 1.7 Estimated encounters and incidental mortalities (nominal fish) in NBC AABM troll and sport fisheries for 2002-2009. Mortality estimates of fish released in troll and sport fisheries include drop-off mortality.

| Year |  | Troll |  |  |  | Sport |  | Total Incidental Mortalities |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | IM | 1,283 | 2,075 | 701 | 95 | 2,346 | 3,309 | 7,639 | 2,171 |

${ }^{1}$ Drop-off mortality is computed from landed catch times a percentage that incorporates a gear-specific encounter ratio and release mortality rate.
${ }^{2}$ Releases are reported as 'mixed' sizes. However, since $>90 \%$ of such releases are legal-sized, all reported releases were considered to be legal-sized for the purpose of estimating incidental mortality.

### 1.2.2.2 WCVI Fishery

The estimated total mortality of Chinook salmon in the WCVI AABM fisheries in 2009 was 139,686 nominal fish, including 124,617 Chinook salmon in the landed catch and 15,069 fish from IM (Table 1.8). The estimated IM included 8,729 legal and 6,340 sublegal fish in nominal numbers of fish. The estimates for the commercial troll fisheries in 2009 are based on landed catch multiplied by rates of encounter from previous years. Table 1.8 summarizes encounter and IM estimates for these fisheries by size class during retention. In 2009, a non-retention AABM troll fishery opened in September to collect sublegal Chinook salmon DNA samples.

Table 1.8 Estimated encounters and incidental mortalities (nominal fish) in WCVI troll and sport AABM fisheries. Mortality estimates of fish released in troll and sport fisheries include drop-off mortality.

${ }^{1}$ Legal drop-off mortality is computed from landed catch, incorporating both an encounter ratio and a mortality rate.
${ }^{2}$ Sublegal dropoffs are included with sublegal incidental release mortalities

### 1.3 REVIEW OF ISBM FISHERIES

### 1.3.1 Canadian ISBM Fisheries

ISBM fisheries include all fisheries that harvest or release Chinook salmon in British Columbia under PST jurisdiction outside areas governed by AABM fisheries. In 2009, 204,378 Chinook salmon were harvested in Canadian ISBM fisheries in British Columbia and Canadian sections of the Alsek, Taku and Stikine Transboundary rivers. Total estimated IM in the Canadian ISBM fisheries in 2009 was 22,252 legal and 16,048 sublegal sized Chinook salmon. The distribution of the landed catches and estimated incidental mortalities in Canadian ISBM fisheries are presented in Table 1.9. Historical catches in Canadian fisheries are in Appendixes A2 through A8. Troll and Net catches from 1996-2004 have been updated with data from the Catch Finalization Project. The former Georgia Strait and Fraser River Appendix has been separated into two Appendix tables and the series of Fraser data has been updated from estimates collected from Area staff.

Table 1.9 Landed catch and incidental mortalities in Canadian ISBM fisheries for 2009.

| Region | Fishery | Landed Catch | Release Legal | Release Sublegal | Total IM Legal | Total IM Sublegal | Total Nominal Mortality |

### 1.3.2 Southern U.S. Fisheries Harvest

Southern U.S. fisheries of interest to the PSC, generally those north of Cape Falcon, Oregon, are managed in accordance with legal obligations stemming from treaties between Indian tribes and the United States. In 1974, U.S. v Washington set forth sharing obligations to meet Treaty fishing rights in western Washington. Treaty rights of Columbia River tribes were defined by U.S. v Oregon, and the Columbia River Fisheries Management Plan was implemented in 1977. In reporting these fisheries, fishermen are termed "treaty" if they are fishing under the Native Treaty fishing rights and "non treaty" otherwise. As specified in the 2008 agreement, all southern U.S. fisheries are ISBM fisheries. Historical catches in these fisheries may be found in Appendices A. 8 through A. 14.

### 1.3.2.1 Strait of Juan de Fuca and the San Juan Islands

The preliminary estimate of the 2009 Chinook salmon catch in Strait of Juan de Fuca tribal net fisheries directed at Sockeye salmon is 94. An additional 5 Chinook salmon were taken during the Coho management period. There were no 2009 San Juan Islands net fisheries directed at Sockeye salmon. The preliminary estimate of the 2009 Strait of Juan de Fuca treaty troll fishery is 3,280 Chinook salmon through December. The catch estimate does include catches from Area 4B during the May-September PFMC management period. Historic catch estimates are provided in Appendices A. 8 and A. 9 for the Strait of Juan de Fuca and San Juan areas respectively.

### 1.3.2.2 Puget Sound

The preliminary estimate of the 2009 tribal and non-tribal net fishery harvests in Puget Sound marine areas is 41,246 (38,509 tribal, 2,737 non-tribal) for all marine areas excluding 4B, 5, and 6, 6A, 6B, and 6C in the Strait of Juan de Fuca. Additional tribal net harvest occurred in freshwater fisheries with a preliminary estimate of 27,904. Estimates of the sport catch in 2009 are not yet available. Historic catch tables for Puget Sound exclusive of the San Juans are provided in Appendix A. 10.

### 1.3.2.3 Washington Coast

Tribal commercial and ceremonial and subsistence fisheries harvested a total of 9,619 Chinook salmon in north coastal rivers (Quinault, Queets, Hoh, and Quillayute) in 2009. An additional 48 Chinook salmon were harvested by the Makah tribal fisheries in the Waatch and Sooes rivers.
Harvest in Grays Harbor includes catch from both the Humptulips and Chehalis rivers. The 2009 tribal net fisheries harvested an estimated 2,207 Chinook salmon. The 2009 non-Indian commercial net harvest in Grays Harbor was 1,195 Chinook salmon. Approximately 6,929 Chinook salmon were harvested by non-Indian commercial net fisheries in Willapa Bay in 2009.
From Grays Harbor north, recreational fisheries were implemented based upon pre-season tribalstate agreements and were subject to in-season adjustment. Estimates of sport fishery catches for Washington coastal terminal fishing areas in 2009 are not available. Historic catch estimates for Washington Coastal inside fisheries are shown in Appendix A.11.
Ocean fisheries off the coasts of Washington and Oregon are managed under regulations recommended by the Pacific Fishery Management Council. The estimated catch of Chinook salmon in commercial troll fisheries from Cape Falcon to the U.S.-Canada border in 2009 was 35,100 for both treaty and non-treaty fisheries combined. Estimated catch in the ocean
recreational fishery north of Cape Falcon in 2009 was 15,457 Chinook salmon. Historic catch estimates for U.S. ocean fisheries north of Cape Falcon are shown in Appendix A. 12

### 1.3.2.4 Columbia River

Chinook salmon from the Columbia River are divided into eight stock groups for management purposes. These groups are delineated by run timing and area of origin: (1) spring run originating below Bonneville Dam; (2) spring run originating above Bonneville Dam; (3) summer run originating above Bonneville Dam; (4) fall run returning to Spring Creek Hatchery; (5) fall run originating in hatchery complexes below Bonneville Dam; (6) wild fall run originating below Bonneville Dam; (7) upriver bright fall run; and (8) mid-Columbia bright fall hatchery fish.

In 2009, the total annual harvest for all fisheries (spring, summer and fall) in the Columbia River basin was 283,419 Chinook salmon, which included non-Indian commercial net harvest of 71,372 , sport harvest of 78,311 and treaty Indian commercial, ceremonial and subsistence harvest of 133,736 Chinook salmon.

### 1.3.2.5 Ocean Fisheries, Cape Falcon to Humbug Mountain

Most harvest in ocean fisheries off Oregon's coast is comprised of a mixture of southern Chinook salmon stocks not included in the PSC agreement. These stocks do not migrate north into the PSC jurisdiction to any great extent. Some stocks originating from Oregon coastal streams do migrate into PSC fisheries, including the North Oregon Coastal (NOC) and MidOregon Coastal (MOC) stock aggregates. The NOC stocks are harvested only incidentally in Oregon ocean fisheries, while the contribution of MOC stocks to Oregon ocean fisheries is believed to be much greater. Catch statistics are readily available only for a terminal area troll fishery on one MOC stock at the mouth of the Elk River. Late season (October-December) troll catch in the Elk River terminal troll fishery in 2009 was 293 Chinook salmon.

Recreational catch of these two stock groups occurs primarily in estuary and freshwater areas as mature fish return to spawn and is reported through a "punch card" accounting system. These data are only available more than two years after the current season. Therefore, we can only report the riverine and estuarine sport catch though 2008 for the NOC and MOC groups. The 2008 punch card estimate of estuary and freshwater catch for the NOC and MOC groups is 17,547 Chinook salmon. Historic catch estimates for the Elk River troll fishery and the estuary and freshwater sport fisheries targeting on MOC and NOC stocks are shown in Appendix A.14.

### 1.4 ESTIMATES OF INCIDENTAL MORTALITY FOR SOUTHERN U.S. FISHERIES

Table 1.10 shows estimates of incidental mortalities for Washington Coastal and Puget Sound fisheries. Sources of estimates are shown in the table footnotes. No estimates of incidental mortalities were provided for 2009 for ocean fisheries south of Cape Falcon or Columbia River fisheries.

Table 1.10 Estimated incidental mortality in Southern US troll, net, and sport fisheries for 2009.

| Fishery | Troll | Net $^{\mathbf{1}}$ | Sport |
| :--- | :--- | :--- | :--- |
| Strait of Juan de Fuca | $280^{2,3}$ | 51 | 3,726 |
| San Juan Islands | 0 | 3,135 | 3,176 |
| Puget Sound | 0 | 804 | 34,906 |
| Washington Coast | 0 | 562 | 200 |
| North of Cape Falcon | $15,911^{3}$ | 0 | $2,338^{3}$ |

${ }^{1}$ Assume 3\% net dropout rate.
${ }^{2}$ Estimates from FRAM.
${ }^{3}$ Estimates from direct observations.

## 2 CHINOOK SALMON ESCAPEMENTS

### 2.1 INTRODUCTION

The Agreement (Pacific Salmon Treaty Fishing Annexes \& Related Agreements, June 30, 1999) established a Chinook salmon management program that:
"introduces harvest regimes that are based on estimates of Chinook salmon abundance, that are responsive to changes in Chinook salmon production, that take into account all fishery induced mortalities and that are designed to meet MSY or other agreed biologically-based escapement objectives"
This chapter compares annual escapement estimates with maximum sustained yield (MSY) or other accepted biologically-based escapement goals established for Chinook salmon stocks. The CTC has reviewed and accepted escapement goals for 24 stocks included in this report. For these stocks, the CTC can evaluate stock status in relation to the accepted goals. For stocks without accepted goals, the CTC must rely on the time series of escapement data and the agency commentary for the individual stocks to provide a perspective on stock status and escapement trends.

Annual reports prior to 2006 included a section on the framework used for escapement assessments and narratives for each stock that included a description of escapement methodology, escapement goal basis, and agency comments. For these more detailed stock narratives and descriptions of escapement methods, please refer to the 2004 Catch and Escapement Report (CTC 2005a).

### 2.1.1 MSY or Biologically-Based Escapement Goals

### 2.1.1.1 Origin of Goals

Escapement goals accepted by the CTC were based on analyses that followed the guidelines developed in the CTC escapement goal report (CTC 1999). In the stock-specific narratives presented with the escapement graphs, the agencies may refer to agency goals, but only CTCaccepted escapement goals and ranges (in gray shading) are shown on the escapement graphs and used for evaluation. Table 2.1 presents the status of escapement goal reviews by the CTC for stocks identified as escapement indicator stocks.

Table 2.1. PSC Chinook salmon escapement indicator stocks, where shading indicates that there is not a CTC accepted escapement goal for PSC assessment of stock status.

1 The escapement indicator stocks listed in the Annex tables for this group are Upper Fraser, Middle Fraser, and Thompson. The Fraser
spring/summer group is split into these 4 escapement indicators to represent the stock group by life history type rather than geographically.
2 An escapement goal was established for the Cowichan in 2005; a goal for Nanaimo is still pending.

### 2.2 ESCAPEMENT GOAL ASSESSMENTS

The Agreement directs the CTC to "report annually on the escapement of naturally spawning Chinook salmon stocks in relation to the agreed escapement objectives referred to below, evaluate trends in the status of stocks, and report on progress in rebuilding of naturally spawning Chinook salmon stocks" (Annex IV, Chapter 3, Paragraph 1.b.iii). In this report, escapement assessments include stock specific graphs of escapements and commentary, presented to provide a perspective on stock status and escapement trends through 2009. More detailed commentary for each stock can be found in previous CTC catch and escapement reports, e.g. CTC (2005a).
The escapement goals and 2009 escapements for the 25 stocks with CTC accepted escapement goals are listed in Table 2.2. For 12 of these stocks, the agency escapement goal is defined as a range; for the remaining 13 stocks, the escapement goal is defined as a point estimate. In 2009, escapements were within the goal range for 3 stocks, above the range or $\mathrm{S}_{\text {MSy }}$ point estimate for 8 stocks, and below the goal for 14 stocks.
The CTC has now assessed the status of stocks with CTC-accepted goals for return years 19992009. Over this time period, the number of stocks with CTC-accepted goals has increased from 16 to 25 (Figure 2.1). From 1999-2008, the percentage of stocks below escapement goals or goal ranges has varied from $4 \%$ to $54 \%$. In 2009, $52 \%$ of stocks were below goals or goal ranges.

Table 2.2. Escapement goals and 2009 escapements for PSC Chinook salmon escapement indicator stocks with biologically-based goals accepted by the CTC.

| Stock | Region | Stock Group | Escapement Goal | $2008$ <br> Escapement | 2009 Escapement | 2010 <br> Forecast |

| Siuslaw | ORC | NOC | 12,925 | 11,119 | 14,094 | 21,848 |

The CTC has now assessed the status of stocks with CTC-accepted goals for return years 19992009. Over this time period, the number of stocks with CTC-accepted goals has increased from 16 to 25 (Figure 2.1). From 1999-2008, the percentage of stocks below escapement goals or goal ranges has varied from $4 \%$ to $54 \%$. In 2009, the percentage of stocks below goals or goal ranges was $52 \%$. Of the 13 stocks below goal, 9 stocks (69\%) were within $15 \%$ of the target goal; the stocks at more than $15 \%$ below goal were the Blossom, Cowichan, Queets spring/Summer, and the Nehalem stocks.

Figure 2.1. Number and status of stocks with CTC-accepted escapement goals for years 19992009.

### 2.3 PARAGRAPH 13 ESCAPEMENT ANALYSIS

Paragraph 13 of the 2008 Agreement describes a process to implement additional management actions in AABM and ISBM fisheries if the management as prescribed in paragraphs 8 and 10 fail to meet MSY or other biologically-based escapement objectives. Paragraph 13 details a process for evaluating stock groups and indicator stocks listed in Attachments I-II to determine if additional management actions should be implemented in AABM fisheries. If additional management action is required, relevant ISBM fisheries for stocks also listed in Attachments IV and V would commensurately be reduced to increase the escapements of the depressed Chinook salmon stocks within the stock groups triggering the additional management actions. The CTC is to notify the Commission of any proposed fishery restrictions to be implemented under Paragraph 13 at the February Annual Meeting.

Additional management actions for SEAK or NBC AABM fisheries would reduce Table 1 catch limits by $10 \%$ if a majority of stocks with agreed management objectives in at least two of the stock groups listed in Attachment I and II of the Chinook Annex were observed:

- to be at least $15 \%$ below their escapement goal management objectives for the past year and are forecast to be at least $15 \%$ below their escapement goal objectives in the upcoming year; or
- were observed to be at least $15 \%$ below their escapement goal objectives for the past two consecutive years (unless a forecast for escapement will exceed the escapement objective in the coming year).
If three or more stock groups in Attachments I and II meet the criteria to trigger additional management action, Table 1 catch limits in the relevant AABM fishery would be reduced by 20\%.

For the WCVI AABM fishery, Attachment III of the 2008 Agreement lists stock groups applicable to the obligations defined in paragraph 13. However, in consideration of the 30\% reduction in catch limits for the WCVI AABM fishery, the 2008 Agreement states that additional actions will not be taken for this fishery except as otherwise may be agreed by the Commission.

The CTC is assigned by the 2008 Agreement to provide a review of Attachments I-V by 2014 or earlier, to determine if the current lists of stock groups continue to be appropriate, if there are new criteria that could be employed to revise stock group listings for each attachment, and whether any changes to the Attachments proposed by a Party may be appropriate. In the interim, the CTC in this report provides an evaluation of the stocks listed in Attachments I-III in relation to the criteria described in Paragraph 13.

In Table 2.3, the CTC summarizes the performance of the stock groups and the criteria for initiating additional management action in regards to Paragraph 13, based upon observed escapements and exploitation rates through 2009 and stock forecasts for 2010. For SEAK and NBC AABM fisheries, the stock groups in Attachment I and II are identical, and thus are combined in Table 2.3. All stocks relevant to Paragraph 13 decisions for SEAK and NBC AABM fisheries have escapement based management objectives. Although not meeting management objectives does not automatically trigger reductions in the WCVI AABM fishery, the CTC included an evaluation of the stock groups in Attachment III to inform the Commission of the performance of the stock groups in Attachment III in relation to the provisions of Paragraph 13. For the WCVI AABM fishery, stocks in the Puget Sound Summer/Fall stock group include three stocks with exploitation rate management objectives.

No stock groups listed in Attachment I-III met the criteria for triggering additional management action under Paragraph 13 for either the 2008 and 2009 observed values or the 2009 and 2010 forecast values (Table 2.3). However, the CTC could not evaluate if any of the stocks met the conditions in Paragraph 13(d), because harvest levels for ISBM fisheries were not yet available for 2009. Only one stock with an agreed escapement objective, the Nehalem in the NOC stock group, was more than $15 \%$ below the management objective in both 2008 and 2009. The Nehalem was also the only stock with an agreed escapement objective and a forecast below its threshold in 2010. The other two NOC stocks are forecast to be above goal in 2010.

Only 5 of the 10 different stock groups in Table 2.3 have stocks with agreed management objectives that can be evaluated for triggering additional management action. Of the 11 stocks with agreed escapement objectives, forecasts for 2010 were available for only 7 (Table 2.3). There is clearly a need to develop management objectives and forecast capabilities for more of the stocks included in Attachments I-III to improve the efficacy of the Paragraph 13.

This analysis was done well after the February timing required by the 2008 Agreement for the CTC to notify the Commission of any proposed fishery restrictions to be implemented under Paragraph 13 for the 2010 fishing season. Also, the CTC has not yet set the standards for precision and accuracy for forecasts and predictions used to develop Table 2.3. These data standards will be required before the evaluations that rely on forecasts can be used to recommend additional management action. However, the CTC has carried out the evaluation of the Paragraph 13 criteria, with the exception 13(d) and (e), to provide insight into current status of stocks in relation to the criteria and to identify data needs for the application of Paragraph 13. To meet the timing requirement for implementation of Paragraph 13, the CTC will need by the February Annual Meeting a) escapement and exploitation rate estimates for the prior year for stocks included in Paragraph 13 Attachments I-V; and b) projections of exploitation rates and forecasts of escapements for the coming year for these same stocks.

The Commission has assigned the CTC to review Attachments I-V and to provide recommendations to the Commission. In its review, the CTC may consider the schedule of needed information for evaluation of the stock group criteria to determine how early in the annual cycle recommendations for additional management actions under Paragraph 13 can be provided to the Commission.

Table 2.3 Evaluation of criteria for initiating additional management action in regards to Paragraph 13 of the Chinook Chapter of the 2008 Agreement. NA indicates the stock group cannot be evaluated because an insufficient number of stocks in the group have agreed escapement objectives, or that forecasts were not provided to the CTC for stocks with agreed escapement objectives.

|  | Stock Group |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: |

### 2.4 STOCK SPECIFIC GRAPHS AND COMMENTARIES

Graphs of time series of escapements and terminal runs for Chinook salmon stocks are included in sections for Alaska, Canada, and Washington/Columbia River/Oregon. A limited commentary is also provided for each stock; more details on historical assessments and escapement goals for individual stocks are available in CTC (2005a). Each graph contains the name of the stock and the type of data depicted (total escapement, index counts, terminal runs, etc.). For the graphs that include estimates of the terminal run size, the harvests in terminal runs, in some cases, include both jacks and adults, whereas the escapement is usually reported in adults. The $x$-axis represents calendar years. All escapement goals accepted by the CTC are shown except for the LGS stock group because this group includes both the Cowichan and Nanaimo stocks and only the Cowichan has a CTC accepted goal. Historical escapement and terminal run data are provided for SEAK stocks in Appendix B.1, for Canadian stocks in Appendix B.2, for Puget Sound in Appendix B.3, Washington Coastal stocks in Appendix B.4, for Columbia River stocks in Appendix B. 5 and Oregon Coastal stocks in Appendix B.6.

### 2.4.1 SEAK/TBR Stocks

Of the 11 SEAK/TBR stocks included in the escapement assessment, the Situk, Alsek, Chilkat, Taku, King Salmon, Stikine, and Unuk rivers and Andrew Creek include estimates of total escapement of large fish, Chinook salmon > 659 mm mid-eye to fork (MEF) length. Escapement estimates for the Chickamin, Blossom, and Keta rivers are index counts of large fish. These indices are enumerated from foot/aerial helicopter surveys that represent a fraction (one-third to one-fifth) of the total escapement. Except for the Chilkat River, survey methods have been standardized for all systems since 1975. The assessment of Chilkat River Chinook salmon was standardized in 1991 as an annual mark-recapture estimate of escapement. Escapement goals have been defined as a range for the SEAK/TBR stocks, shown by the grey shaded area on the graphs.

The Situk River is a small non-glacial system that supports a moderate run of outside-rearing Chinook salmon. Escapements are based on weir counts minus upstream sport fishery harvests (if any) estimated from an on-site creel survey and a postseason mail-out survey. The weir has been operated annually since 1976, and was also operated from 1928-1955.

Commentary: The Alsek River is large Transboundary glacial system that supports a moderate run of outside-rearing Chinook salmon. In previous reports, index escapements using a weir operated at the Klukshu River were presented for this stock. These have been replaced with estimates of total escapement drainage wide, including direct mark-recapture estimates for 19982004. All other years are Klukshu River weir counts expanded by the average expansion factor from 1998-2004. A revised goal of 3,500 to 5,300 total spawners was accepted by the CTC during this cycle, based on analysis in Bernard and Jones (2010).

Commentary The Taku River is a large Transboundary glacial system that supports a large run of outside-rearing Chinook salmon. In 1989, 1990, and 1995-2009 escapements were estimated using mark-recapture methods. In other years since 1975, aerial counts were expanded by a factor of 5.2, the 5-year average of the ratio of the mark-recapture estimates to aerial survey counts (McPherson et al. 2000). A revised goal of 19,000 to 36,000 large Chinook salmon (age.3 to -.5 fish) was accepted by the CTC and TBR Panel during this cycle, based on the analysis in McPherson et al. (2010).

Commentary The Stikine River is a large Transboundary glacial system that supports a large run of outside-rearing Chinook salmon. From 1975 through 1984 index escapements were made using survey counts and since 1985 counts were made using a weir at the Little Tahltan River. Since 1996 mark-recapture experiments were conducted annually to estimate total escapement. These studies indicate the weir counts represented $17 \%$ to $20 \%$ of the total escapement (Pahlke and Etherton 1999). In 2009, the estimated escapement was $90 \%$ of the lower end of the escapement goal range due to poor survival conditions. No directed fisheries were operated on this stock in 2009 because preseason and inseason forecasts correctly identified a very low run size.

Commentary The Chilkat River is a moderate-sized glacial system moderate run of insiderearing Chinook salmon. Since 1991, escapements have been estimated annually using markrecapture methods (Ericksen and McPherson 2003). The current biological escapement goal of 1,750 to 3,500 was formally accepted by the CTC in 2005.

Commentary: The King Salmon River is a small non-glacial system that supports a small run of inside-rearing Chinook salmon. Escapements are based upon weir counts from 1983 to 1992 and expansions of index counts from 1971 to 1982 and 1993 to 2006. The 10 years of weir data showed that on average the escapement was 1.52 times the index count (McPherson and Clark 2001). In 2009, the estimated escapement was $91 \%$ of the lower end of the escapement goal range due to poor survival conditions.

Commentary Andrew Creek, a tributary of the lower Stikine River, is a small non-glacial system that supports a moderate run of inside-rearing Chinook salmon. Escapements are based upon weir counts from 1976 to 1984 and expansions of index counts in 1975 and 1985 to 2006. Four years of concurrent weir and index count data were used to estimate the expansion factor of 1.95. In 2009, the estimated escapement was $97 \%$ of the lower end of the escapement goal range due to poor survival conditions.

Commentary: The Unuk River is a moderate-sized glacial system that supports a moderate run of inside-rearing Chinook salmon. Indices of escapement since 1977 are based on the sum of peak index counts from six main tributaries (Pahlke 2003). Mark-recapture studies were implemented in 1994 and annually since 1997 (Weller and McPherson 2003). The current estimated expansion factor is 4.87 for index counts from 1977-1996. The CTC accepted an escapement goal range of 1,800 to 3,800 total large spawners for this stock during this cycle, based on the analysis in Hendrich et al. (2008).

Commentary: The Chickamin River is a moderate-sized glacial system that supports a moderate run of inside-rearing Chinook salmon. Indices of escapement since 1975 are based on the sum of peak index counts from eight main tributaries (Pahlke 2003). Mark-recapture studies were performed in 1995, 1996, and 2001-2005. The current estimated expansion factor is 4.6 for index counts.

Commentary: The Blossom River is a small-sized non-glacial system that supports a small run of inside-rearing Chinook salmon. Indices of escapement since 1975 are based on the sum of peak index counts (Pahlke 2003). Mark-recapture studies performed in 1998 and 2004 to 2006 estimated an expansion factor range of 2.0 to 4.0. The agency agreed expansion factor is 3.87. In 2009, the survey count was $49 \%$ of the lower end of the existing goal range, due to poor survey and survival conditions.

Commentary: The Keta River is a small-sized non-glacial system that supports a small run of inside-rearing Chinook salmon. Indices of escapement since 1975 are based on the sum of peak index counts (Pahlke 2003). Mark-recapture studies were performed 1998 to 2000 (Freeman et al. 2001). The estimated expansion factor is 3.0 for index counts. In 2009, the estimated escapement was $88 \%$ of the lower end of the escapement goal range due to poor survey and survival conditions.

### 2.4.2 Canadian Stocks

Since the beginning of the Chinook salmon rebuilding program of the 1985 PST, escapement goals for Canadian Chinook salmon stocks were generally based on doubling the average escapements recorded from 1979-1982. The doubling was based on the premise that Canadian Chinook salmon stocks were over-fished and that doubling the escapement would still be less than the optimal escapement estimated for the aggregate of all Canadian Chinook salmon populations (see stock-recruitment curve in "Technical Basis of PSC Catch Ceilings," Figure 1, Attachment 4, PSC file 72006; PSC Office, Vancouver, BC). Doubling was also expected to be a large enough change in escapements to allow detection of the change in numbers of spawners and the subsequent production. The escapement goals of the Canadian stocks are currently being reviewed.

Commentary: The Yakoun River is the only significant Chinook salmon-producing stream on Haida Gwaii (the Queen Charlotte Islands). Chinook salmon spawn primarily at the outlet of Yakoun Lake and are a summer-run stock. Visual estimates of escapement were made by foot surveys of the system. These estimates were then expanded into a total estimate of spawning escapement in the system. The effort spent on escapement surveys declined to 2005 and their accuracy (i.e. ability to estimate the actual escapement) was unknown. Escapement estimates are thought to have exceeded 5,000 Chinook salmon since 2005. However the abundance index has not been continued.

Commentary: The Nass River is the largest river in Area 3, representing a group of approximately 25 streams in Area 3. Prior to 1992, CDFO observations of escapement were based on visual counts. Mark-recapture programs have been conducted since 1992 by the Nisga’a Fisheries to estimate total spawning escapement in the Nass River. The Nass markrecapture program uses two fish wheels at Gitwinksihlkw (GW) in the lower Nass canyon to apply tags and two wheels at Grease Harbor in the upper canyon and the Meziadin River fishway for recovery. A modified Petersen model was used to estimate the total population of Chinook salmon past the tagging location. Tags were also recovered in upriver fisheries and on the spawning grounds. Spawning escapements were calculated as the estimated Chinook salmon population past GW from the mark-recapture studies, less upriver catches in sport and First Nations fisheries. Three tributaries with Chinook salmon populations enter the Nass River below GW. Visual estimates augmented by fence counts of the Kincolith River in 2001, 2002, 2005 and 2007 were used to estimate Nass River Chinook salmon escapements below the fish wheels.

Commentary The Skeena Chinook salmon escapements above represent 40 streams within the Skeena watershed which are consistently surveyed. The Skeena supports over 75 separate Chinook salmon spawning populations, but three (Kitsumkalum, Morice, and Bear Rivers) account for about 70\% of the total abundance. A second group of populations (Ecstall, Kispiox, and Babine rivers) have annual returns ranging from 1,000 to 5,000 spawners, and comprise about $13 \%$ of Skeena returns. Escapement estimates are generally based on visual observations from helicopter, fixed wing aircraft and/or from stream walking surveys. Fish counting weirs are present on the Babine, Sustut and Kitwanga Rivers. The Kitsumkalum River is the exploitation rate indicator stock for the Skeena Chinook salmon complex. Spawning escapements in the Kitsumkalum have been estimated using a mark-recapture program since 1984.

Commentary The Area 8 Chinook salmon stock consists of seven non-enhanced systems, but the Dean River is the main spawning population. Of all Chinook salmon- producing streams in Areas 5 to 10, the Dean is the best indicator in terms of consistent survey coverage and methodology. Chinook salmon returning to the Dean River have early-summer timing and most spawn in the lower river by July. Up until 2000, counts of spawning Chinook salmon were made during 1-3 surveys and the peak count used as the escapement index. Survey counts were sometimes expanded to account for sections of the river that could not be surveyed in any year, but the counts were not extrapolated to total escapement of Chinook salmon to the river. Since 2001, the annual number of aerial surveys has increased, allowing the calculation of area-under-the-curve (AUC) escapement estimates. In some years viewing conditions were poor and did not result in counts necessary to produce an AUC estimate. In these years maximum likelihood estimates were used to produce estimates as was the case in $2004(3,500)$. A Chinook salmon mark-recapture program was initiated on the Dean River in 2006 to generate expansion factors for converting the current spawner indices (AUC estimates from helicopter flights) into estimates of total escapement. The preliminary estimate of escapement based on the mark-recapture program was 5,478 in 2006 compared to the maximum likelihood estimate of 3,689 . For the
purposes of this report however, the index of escapement is reported in the figures.

Commentary: The Wannock, Chuckwalla, and Kilbella Rivers are the primary Chinook salmon streams in Area 9 (Rivers Inlet area). Small tributaries of Owikeno Lake also contain Chinook salmon but these populations are much smaller. The Wannock River contains the largest Chinook salmon population, averaging 5,200 Chinook salmon in the 1990s, while the Chuckwalla and Kilbella together averaged around 300. The Wannock River drains Owikeno Lake, is about six kilometers long, and is wide and turbid. The Chuckwalla and Kilbella rivers are much longer, drain from coastal mountains, and their visibility is much more variable depending on local weather (glacial flour to clear). The timing of these stocks also differs: the Wannock has late summer/fall run timing; the other two are early summer Chinook salmon stocks. Escapement estimates in the Chuckwalla and Kilbella rivers are derived from aerial surveys, whereas Wannock escapement is derived from expansions of carcass counts to estimate spawning escapement.

Commentary: The WCVI index represents the sum of escapements for six rivers (Marble, Tahsis, Burman, Artlish, Kaouk, and Tahsish), which were chosen to provide an 'index' of escapement for wild WCVI stocks in general. These stocks were chosen based on historical consistency of data quality. CDFO has developed a 14 stream expanded index which includes escapements to the six stream index plus the following WCVI streams: Colonial/Cayegle Creeks (Area 26), Leiner (Area 25), Megin, Bedwell/Ursus, Moyeha (Area 24) and Sarita, Nahmint (Area 23), and San Juan (Area 21). In 2005, the Colonial/Cayegle escapement was not available, and was therefore not included in the 14 stream index. Since 2007, a mark-recapture program was conducted on the Burman River, in addition to the regular swim and foot surveys. However, the escapement estimate used for the index followed the same methodology since 2005.

Commentary: The Upper Strait of Georgia (UGS) stock index consists of four river systems (Klinaklini, Kakweiken, Wakeman, Kingcome) in Johnstone Strait mainland inlets and the Nimpkish River on northeast Vancouver Island. The accuracy of escapement estimates in the mainland inlet systems is likely poor due to low visibility of glacial systems, remote access, and timing of surveys. Escapement estimates have primarily been based on aerial counts which may not encompass Chinook salmon run-timing. Swim surveys and stream walks have been conducted in the Nimpkish River. A fish wheel program implemented on the Klinaklini in 1997 was discontinued in 2004. Based on the portion of the assessment program that continued in 2005, estimated abundance in 2005 was assumed to be the same as in 2004. Since 2006, the accuracy of the escapement estimate for the Klinaklini is considered to be very poor.
Consequently, escapement for this stock was not included in the 2006 or 2007 index. No fish were observed in the Kakweiken River in 2006 or 2007.

Commentary: Lower Strait of Georgia (LGS) rivers monitored for naturally spawning fall Chinook salmon escapement are the Cowichan and Nanaimo rivers. Total Chinook salmon returns to the Cowichan and Nanaimo rivers have been estimated since 1975. Prior to 1988, escapement estimates from the Cowichan River were derived from swim and aerial surveys. This approach was also used for the Nanaimo River prior to 1995. Since 1988 a counting fence has been used in the Cowichan River, and since 1995 carcass mark-recapture surveys have been used in the Nanaimo River. Since 2005, AUC estimates have been used in the Nanaimo River and a tagging study was used to determine survey life in 2006. An escapement goal of 6,500 for the Cowichan River was accepted by the CTC in 2005; a goal for the Nanaimo is still pending.

### 2.4.3 Fraser River Stocks

The Fraser River watershed is the largest Canadian producer of Chinook salmon. Fraser Chinook salmon consist of many local populations as described in CTC (2002b).

Much of the knowledge about the status of Fraser Chinook salmon is based on spawner escapement data. Most data are from visual surveys, which are generally biased low, although many estimates are considered to be reasonably precise. Visual survey data are generated from aerial surveys and the escapement estimate is usually obtained by dividing the peak count by 0.65 (Farwell et al. 1999). The CDFO continues to evaluate the appropriateness of this expansion factor and AUC methodology through calibration studies. Counting fences and mark-recapture projects exist for some systems, although most of the time series of escapement data from these projects are relatively short.

For populations other than the Harrison River, habitat-based models are being developed to estimate spawning capacity and spawner abundance producing maximum sustained yield. This habitat-based assessment will initially focus on predictive models based on Chinook salmon stock-recruitment relationships, although other habitat-based approaches will also be considered.

Commentary: The Fraser Spring-Run Age 1.3 aggregate includes the Upper Pitt River and Birkenhead River stocks in the Lower Fraser, and the spring-run stocks of the Mid and Upper Fraser, North Thompson, and South Thompson, but excluding those of the Lower Thompson tributaries (CTC 2002b). Escapements improved slightly again in 2009, however, they still failed to exceed the parental brood escapement levels in 2004. Escapement to the aggregate was estimated at 24,150 in 2009; roughly $76 \%$ of the brood year escapement in 2005. .

Commentary: The Fraser Spring-Run Age 1.2 aggregate includes six smaller body size populations that spawn in the Lower Thompson River tributaries, Louis Creek of the North Thompson and the spring-run fish of Bessette Creek in the South Thompson (CTC 2002b). . Escapements again declined substantially in 2009, and cumulatively represent the lowest levels ever recorded for this aggregate (911), and only 23\% of the 2005 parental brood escapements. Escapements were critically low at Louis Creek (6) and Coldwater River (26), while Nicola was also the poorest on record at 479.

Commentary: The Fraser Summer-Run Age 1.3 aggregate includes 10 populations, spawning in large rivers, mostly below the outlets of large lakes. These include the Nechako River Chilko and Quesnel rivers in the mid Fraser and the Clearwater River in the North Thompson watershed (CTC 2002b). Escapement surveys of the Stuart River and North Thompson River were discontinued in 2004 due to unreliable counting conditions. Escapements in 2009 again improved slightly over 2008; however they still represent significant declines when compared to the brood year escapements in 2004. Aggregate escapement was estimated at 20,619, roughly $67 \%$ the 2004 parental brood escapement.

Commentary: The Fraser Summer-Run Age 0.3 aggregate includes six populations spawning in the South Thompson watershed upstream of Kamloops and one in the lower Fraser. These include the Middle Shuswap, Lower Shuswap, Lower Adams, Little River and the South Thompson River mainstem, in the BC interior, and Maria Slough in the lower Fraser (CTC 2002b). Escapements to the Summer Run Age 0.3 aggregate were modest $(86,443)$ in 2009,
although they declined from levels observed in $2008(106,539)$. The 2009 escapements represent approximately $96 \%$ of the parental brood year escapements in 2005.

Commentary: The Fraser late stock is dominated by fall returning Harrison-origin Chinook salmon that includes natural spawners in the Harrison River and Harrison-origin fish that were introduced to the Chilliwack River. Since 1984, mark-recapture studies have been conducted annually on the Harrison River to obtain reliable estimates of spawning escapements. Estimates of fall Chinook salmon escapement to the Chilliwack River are based on a procedure long established by the Chilliwack Hatchery staff for expanding the number of carcasses counted in standardized reaches of the river. Spawning escapements to the Harrison River in 2009 were estimated to be 70,119 adult Chinook salmon, and 86,282 jacks. Total fall Chinook salmon escapements to the Chilliwack River were estimated to be 21,308 adults and 13,465 jacks.

## Washington, Oregon and Columbia River Stocks

The PSC escapement indicator stocks in Washington, Oregon, and Idaho are separated into five groups: Puget Sound, Washington Coastal, Columbia River, North Oregon Coastal, and Mid Oregon Coastal. The indicator stocks include a variety of run timings and ocean distributions.

Biologically based escapement goals have been reviewed and accepted by the CTC for three fall stocks (Queets, Quillayute, Hoh), two Spring/summer stocks (Queets, Hoh), three Columbia River stocks (Lewis, Upriver Brights and Columbia River summer), and three Oregon coastal stocks (Nehalem, Siletz and Siuslaw).

Commentary: The Nooksack spring Chinook management unit includes early-timed Chinook populations returning to the North and South forks of the Nooksack River. Because the 2009 escapement of natural-origin Nooksack early Chinook was projected pre-season to be below the lower abundance threshold (LAT) of 2,000 natural-origin spawners, the critical exploitation rate ceiling (CERC) of $6.6 \%$ in southern U.S. fisheries was used in pre-season planning (See WDFW and PSTT (2010) for details on 2009 objectives for all Puget Sound Chinook units). The preseason projection of southern U.S. ER on Nooksack early Chinook was $2.3 \%$. Post-season exploitation rate (ER) estimates are not yet available.

Total spring Chinook escapement to the Nooksack is estimated by a combination of redd count and carcass count expansions. In 2009 total escapement was estimated to be 2,356 (1,903 to the North Fork and 453 to the South Fork). Carcass sampling and otolith analysis of carcasses in the North Fork showed that an estimated 246 of the 1,903 Chinook were natural-origin recruits. DNA analysis of carcasses in the South Fork showed that an estimated 45 of the 453 Chinook were South Fork natural-origin, with the remainder being a mix of hatchery-origin, North Fork natural-origin, and fall stock natural-origin recruits.

Commentary The Skagit spring Chinook management unit includes early-timed Chinook populations returning to the Upper Sauk, Cascade, and Suiattle rivers in the Skagit basin. The Upper Management Threshold (UMT) for Skagit spring Chinook is 2,000. In 2009 the conservation objective for Skagit springs was an AEQ exploitation rate in all fisheries not exceeding $38 \%$. While a postseason estimate is not yet available, the preseason projection for 2009 was for a total rate of $33.5 \%$.

Due to changes in spawning index areas, beginning in 1992 for the Cascade stock and 1994 for the Sauk and Suiattle stocks, escapements are not directly comparable to previous numbers. Escapement is estimated by expansion of total redd counts for the season. The 2009 total escapement estimate for Skagit spring Chinook was 978 spawners.

Commentary: The Skagit River summer/fall Chinook management unit includes the Upper Skagit summer, Sauk summer, and Lower Skagit fall Chinook populations. The UMT for Skagit summer/fall Chinook is 14,500. In 2009, the conservation objective for this unit was an AEQ

ER in all fisheries not exceeding 50\%. The preseason projected total ER was $48.6 \%$. The postseason estimate is not yet available.

Escapement of Skagit summer/fall Chinook was estimated using expansion of redd counts from helicopter surveys of mainstem areas and foot surveys of smaller tributaries. Total escapement to the system in 2009 was estimated to be 6,955 spawners.

Commentary: The Stillaguamish Chinook management unit includes the summer Chinook population spawning in the North Fork, and the fall Chinook population spawning in the South Fork and Mainstem of the Stillaguamish. The UMT for the management unit is 900 naturalorigin spawners. In 2009 the conservation objective for Stillaguamish Chinook was an AEQ ER in all fisheries not exceeding $25 \%$. While a postseason estimate is not yet available, the preseason projection for 2009 was for a total rate of $22.7 \%$.

Escapement estimates for Stillaguamish Chinook were based on redd-count expansions. Total natural spawning escapement in 2009 was estimated to be 1,001. The North Fork summer Chinook estimate was 958 fish, of which 431 were natural-origin. An additional 156 fish were collected for use as broodstock to maintain a CWT indicator program and to augment natural production. The South Fork fall escapement estimate was 43 fish. No estimate of hatchery/natural-origin composition is available.

Commentary The Snohomish Chinook management unit includes the Skykomish and Snoqualmie summer/fall Chinook populations. The UMT for the management unit is 4,600 natural-origin spawners. In 2009, the management objective for Snohomish Chinook was the CERC of $15 \%$ in southern U.S. fisheries, due to the projected rate in northern fisheries exceeding the difference between the unit's rebuilding exploitation rate and critical exploitation rate ceilings (WDFW and PSTT, 2010). The pre-season projected ER in southern U.S. fisheries was 14\%.

Escapement was estimated using expansion of redd counts conducted by a combination of helicopter, float, and foot surveys, and from fish counts at the Sunset Falls fishway. Escapement was estimated to be 1,414 for the Skykomish population and 895 for the Snoqualmie population, for a total of 2,309 . No estimate of natural/hatchery-origin composition is available.

Commentary The Lake Washington Chinook management unit includes the Cedar River and North Lake Washington tributary fall Chinook populations. The UMT for Cedar River Chinook in 2009 was 1,200 natural-origin spawners. The management objective in 2009 was an AEQ ER rate in pre-terminal southern U.S. fisheries not exceeding 15\% on Cedar River Chinook. The pre-season projection was for a southern U.S. pre-terminal ER of 10.7\%.

Chinook escapement in the Cedar River is estimated using expansion of total redd counts. In 2009, escapement was estimated to be 713 Chinook. Approximately 20\% of those spawners were marked hatchery strays. Escapement to the North Lake Tributaries is estimated using live counts and area under the curve (AUC) methods, and counts of fish passed above the rack at the Issaquah Hatchery. Natural spawning escapement was estimated to be 1,161, with an additional 847 released above the hatchery rack. Hatchery/natural-origin composition estimates are not yet available for the North Lake Tributary spawners.

Commentary The Green River Fall Chinook management unit consists of a single population spawning in the mainstem Green River and two of its major tributaries. The UMT for the population is 5,800 spawners. In 2009, pre-terminal southern U.S. fisheries were planned for an ER not to exceed 15\% (projected to be 10.7\%), and terminal fisheries were planned to allow the escapement goal of 5,800 to be met.

Escapement to the Green in 2009 was estimated using an expansion of redd counts. Redd surveys were complicated by escapement of pink salmon in excess of 2 million to the system, which interfered with counts of Chinook redds, and shortened redd life to less than 7 days. Total escapement was estimated to be 688 Chinook, the lowest estimate in recent history. Because escapement was small, the 2009 estimate was based on a complete census of redds, rather than by the index expansion method used in years of higher abundance. Despite the uncertainty caused by the large pink salmon abundance, this low estimate of natural escapement reflects a real decrease in escapement, and was likely the result of two factors. First was the small natural smolt outmigration produced by the 2006 parent spawning escapement. Second was an unusually low rate of straying of hatchery fish produced by the Soos Creek hatchery to the
spawning grounds. The 2009 return of adult Chinook to the hatchery rack was similar to recent years, yet for reasons unknown, far fewer hatchery-origin fish spawned naturally in the river than in those years.

Commentary Hoko River fall Chinook spawn primarily in the mainstem of the Hoko, with limited spawning in larger tributaries. The UMT for the population is 850 spawners. The 2009 management objective was an ER not exceeding $10 \%$ in southern United States fisheries. Postseason ER estimates are not yet available, but the pre-season projection was an ER of $4.8 \%$ in southern U.S. fisheries.

Chinook escapement to the Hoko is based on redd count expansion. In 2009, total natural spawning escapement was estimated to be 103. An additional 282 Chinook were collected for use as broodstock in the supplementation program.

Commentary: A summer Chinook salmon hatchery program using native stock operated from the mid-1970s to the mid-1980s. Spring Chinook salmon of non-native origin were introduced in a hatchery program in the early 1970s. CWT analyses since then have demonstrated significant straying of these spring Chinook salmon into the summer Chinook salmon spawning population. Estimates from 1991-1995 averaged 47\% hatchery origin strays in the naturally spawning population. In 1996, fry plants were eliminated and the smolt plants were reduced. Summer Chinook salmon are managed for a fixed escapement goal of 1,200 adults and jacks combined (PFMC 2003). The 2009 escapement estimate for summer Chinook salmon was 555.

Commentary: No hatchery production of fall Chinook salmon currently occurs in the Quillayute River basin; the program was discontinued in the late 1980s. Since 1991, the returning run size has fluctuated within a range comparable to run sizes observed prior to 1984. The 2009 escapement estimate was 3,085 , with a total terminal estimate of 5,494 . Terminal fisheries are managed for a harvest rate of $40 \%$, with an escapement floor of 3,000 fish (PFMC 2003). This objective is designed to actively probe at and above estimates of escapements that produce maximum sustained harvest (MSH), while minimizing potential detrimental effects of existing fisheries. Stock production analyses of spawning escapements from 1968-1982 were used to determine the initial escapement floor.

Commentary: Similar to many of the other Washington coastal stocks, Hoh River spring/summer escapements have been relatively stable except for much larger returns in 1988, 1989, and 1990. The terminal return for this stock declined from 1997 to 2000, had rebounded in 2001 before declining again since 2005. Terminal fisheries are managed to harvest $31 \%$ of the river run, with an escapement floor of 900 fish (PFMC 2003). This objective is designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock. Stock production analysis of spawning escapement for brood years 1969-1976 was utilized to determine the initial escapement floor. The 2009 escapement estimate and total run size were 880 and 913 respectively.

Commentary: The natural escapement estimates for the Hoh River fall Chinook salmon include fish taken for broodstock in the 1980s. This stock is managed to harvest $40 \%$ of the terminal run, with an escapement floor of 1,200 spawners (PFMC 2003). This objective is designed to actively probe at and above estimates of the escapements that produce MSH, while minimizing potential detrimental effects of existing fisheries. Stock production analyses of spawning escapements from 1968-1982 were utilized to determine the initial escapement floor. The 2009 escapement
estimate was 2,081. Terminal run size estimate was 3,613.

Commentary: Terminal fisheries are managed to harvest $30 \%$ of the river run size, with an escapement floor of 700 fish (PFMC 2003). This objective is designed to actively probe at and above the estimates of escapement that produce MSH. Since 1990, terminal fisheries have had minimal impact on this stock as returns to the river have rarely exceeded the escapement floor in this time frame. Since 2000, sport anglers have been required to release all Chinook salmon during the summer, and tribal fisheries have been limited to one tribal netting day for ceremonial and subsistence purposes. Stock production analysis of spawning escapement for brood years 1969-1976 were used to determine the initial escapement floor. The 2009 escapement estimate was 495 , with a terminal run size of 495 .

Commentary: For Queets River fall Chinook salmon, the 2009 escapement was 2,909 and the terminal run was 4,061 . Terminal fisheries are managed to harvest $40 \%$ of the river return, with an escapement floor of 2,500 spawners (PFMC 2003). This objective is designed to actively probe at and above estimates of the escapements that produce MSH. Stock production analyses of spawning escapements from 1967-1982 were used to determine the initial escapement floor.

Commentary: The Grays Harbor spring Chinook salmon stock is managed for a fixed natural spawning escapement goal of 1,400 fish (PFMC 2003). This single targeted goal was developed as a MSY proxy. This objective was derived from actual spawning data from the mid- to late 1970s, expanded to include additional habitat not covered by spawner surveys. The 2009 escapement was 1,123 Chinook salmon and the 2009 terminal run 1,348.

Commentary: Grays Harbor fall Chinook salmon are managed for a maximum sustained production escapement goal of 14,600 spawners for the Chehalis and Humptulips systems combined (PFMC 2003). This single targeted goal was developed as an MSY proxy. The objective represents assumed optimal spawner density based on estimated available habitat. The 2009 escapement was 7,166 Chinook salmon. The terminal run was 13,145 Chinook salmon.

Commentary: The upriver spring/Snake River spring/summer Chinook salmon escapement in the graph was calculated as the dam count at Bonneville Dam from January 1 through June 15 multiplied by the estimated proportion wild, minus harvests above Bonneville Dam multiplied by the estimated proportion wild. In 1992, Snake River spring/summer naturally spawning Chinook salmon were listed under the ESA. The interim management goal for the Columbia River Fish Management Plan (CRFMP 1988) for Columbia River Springs was 115,000 hatchery and wild adult Chinook salmon counted at Bonneville Dam and 25,000 naturally produced plus 10,000 hatchery produced adults counted at Lower Granite Dam. Under the 2008-2017 US v OR Management Agreement, fishery impacts on natural origin fish are managed using a harvest rate schedule based on expected river mouth abundance. There is no escapement goal, but under a run size of 27,000, total inriver harvest rates are less than $5.5 \%$.

Commentary: The CTC (1999) developed an interim biologically based MSY escapement goal of 17,857 wild upper-Columbia summer Chinook salmon past Bonneville Dam based on PSC Chinook salmon model data. The methods used to reconstruct the escapements for developing the goal were different than the current methods used to estimate upper-Columbia escapements,
as presented in Appendix B. 5 and graphed above. Hence there is not an escapement goal for these data to be evaluated against. The primary change that occurred for this stock is that run reconstructions are now based on Rock Island dam, rather than Priest Rapids Dam. This changed some of the conversion rates and thus had a ripple effect on run-reconstruction for the entire time series.

Details of the run reconstruction are as follows: 1) Bonneville summer Chinook count minus Zone 6 and upper Columbia catches and incidental mortalities, multiplied by 2) the proportion of the run returning to the Upper Columbia (Priest Rapids dam count as a proportion of the sum of the Priest Rapids and the largest Snake River dam counts), multiplied by the proportion of nonharvested summer Chinook crossing Bonneville that spawned naturally (as calculated by the TAC run reconstruction), and 3) Terminal run is calculated as the Bonneville run plus the catches and incidental mortalities below Bonneville, multiplied by the same two proportions (proportion Columbia and proportion naturally spawning).

The time series is different than in previous reports because incidental mortality data were compiled and subtracted, as were additional harvests by the Colville and Wanapum tribes. In addition, in the last few reports, hatchery strays spawning naturally were excluded in calculating the proportion natural spawners (for consistency with PFMC reporting of natural origin spawners), although they are once again included here, since PSC escapements should include all naturally spawning fish. Finally, in 2009, TAC began using counts at Rock Island to calculate summer Chinook conversion rates, rather than Priest Rapids dam counts, so the entire time series of conversion rates have changed. The data prior to 1999 has changed less than data after 1999 in comparison with previous CTC reports. Consequentially, the CTC agreed upon escapement goal is no longer relevant. Under the 2008-2017 US v OR Management Agreement, the parties agreed to manage upper Columbia River summer Chinook salmon based on an interim management goal of 29,000 hatchery and natural origin adults as measured at the Columbia River mouth, or 20,000 adults (hatchery and wild) at Bonneville Dam. Escapement statistics reported herein (Appendix Table B. 5 and in the figure above) are not relevant to the US $v$ OR Management Agreement.

Commentary: The CTC agreed escapement goal for the Columbia River Upriver Bright Chinook salmon is 40,000 naturally spawning fish past McNary dam. The calculation of Upriver Brights starts with the Chinook salmon count at McNary Dam and then subtracts upstream sport fishery harvest and broodstock collections at Priest Rapids, Ringold, and Lyons Ferry hatcheries. This method implicitly combines the non hatchery Snake River, Yakima River, upper Columbia River, and Hanford Reach populations. For purposes of Washington and Oregon ocean fisheries, and in in-river management, the Snake River component is managed separately based on fish counts at the Lower Granite Dam accounting for hatchery production, and Lyons Ferry brood stock separately from the upper Columbia Hanford Reach section that includes the Yakima River brights. The time series differs from the previous reports primarily because the Priest Rapid Hatchery time series on escapement has been updated, and these estimates updated go back for the last 30 years. In addition subsistence catches have also been accounted in the reported estimates. In recent years stocks had large runsizes in 2003 and 2004, with a decline till 2007. It appears that the stocks are on an increasing run-size trend again.

Commentary: The escapement goal for Lewis River fall Chinook salmon is 5,700 naturally spawning fish. Escapement goal were not met for these stocks in 2007, 2008 and 2009. Both ocean and in-river sport fisheries have taken management actions to respond to these declines in productivity and escapement abundance. However, projections for run sizes in 2010 appear to indicate that escapement goals may be met for this stock.

Commentary: The CTC agreed escapement goal for Deschutes River fall Chinook salmon is 4,532 fish. Escapement data are based on a mark-recapture estimate for the area above Sherars Falls, expanded for redd counts below Sherars Falls. From 2000 through 2007, Confederated Tribes of the Warm Springs (CTWS) performed an entire river mark-recapture experiment to validate the Deschutes River fall Chinook salmon escapement estimates based on the Sherars Falls mark-recapture method. Results of these mark recapture estimates confirm the validity of the traditionally derived estimates and have been incorporated into the derivation of the CTC approved escapement goal in this basin. The entire time series of data were updated in this report based on a comprehensive analysis done by Warm Springs, ODFW and CRITFC staff (Sharma et. al. 2010). As such, we are now only reporting the ODFW mark-recapture methods expanded for redds below Sherars falls. For historic years where redd counts were not censused for the entire river, the overall estimate was adjusted (for more details see Sharma et al. 2010).

Commentary: This stock has been selected for further study under the auspices of the Sentinel Stock Committee's program to improve escapement estimation. Mark-recapture based adult
spawner estimation indicates an escapement of 5,332 Chinook salmon in 2009. Methods directly comparable to those used to generate the agreed to escapement goal for the Nehalem indicate 2009 escapement of 4,070 adult spawners. This is $58 \%$ of the current escapement goal. This is the fourth consecutive year of this stock's failure to meet agreed-to escapement goals. Due to continued failures to meet escapement goal, the terminal sport fall Chinook salmon fishery in the Nehalem was closed in 2009. While a terminal sport fishery is being planned for in the 2010 return year, significant area closures, daily and seasonal bag restrictions are being deployed to assist in the rebuilding of this stock. A creel survey program is planned to measure performance of this terminal sport fishery in 2010. The Nehalem is not forecasted to meet the escapement goal in 2010.

Commentary: This stock has been selected for further study under the auspices of the Sentinel Stock Committee's program to improve escapement estimation. Calibration studies have continued through the 2009 spawning year, thus traditional methods of escapement estimation remain in place until the mark-recapture calibration study is complete. Mark-recapture study of escapement in the Siletz resulted in an independent estimate of 2,270 adult spawners in 2009. Estimates on which the escapement goal was derived differ in method, and thus are not directly comparable to mark-recapture based estimates of escapement. The estimate based upon historically produced habitat expansion methods for 2009 was 2,905 adult fall Chinook salmon. This estimate is within 39 fish of the point estimated goal of 2,944 for the basin. Significant terminal area sport fisheries restrictions which included substantial area closures, restrictive daily and seasonal bag limits are believed to have assisted in the performance of this stock to near (or arguably attainment) escapement goal. Both area restrictions and bag limitations are planned to continue to provide a conservative management approach until such time as this stock is believed to be recovered from recent precipitous declines in escapement. This stock is forecasted to exceed the escapement goal in 2010

Commentary: The estimated spawner abundance in 2009 was 3,301adult Chinook salmon. Methods used to generate escapement estimates in this basin are based on five years (2002-2006) of calibrated peak counts on six standard surveys to mark \& recapture estimates in the Siuslaw basin. The index value is 0.01054 with a SD of $16 \%$. Escapement goal estimate analysis was based upon available habitat expansion estimates used in other basins on the Oregon coast which have been obviated through the improvement of estimation techniques based upon markrecapture estimates. Escapement estimates based on methods used to generate the agreed to goal result in an estimated 14,094 adult spawners. This is the first year in the past 3 in which the Siuslaw fall Chinook salmon return has met or exceeded the agreed-to escapement goal in this basin. Spawner-recruit analysis utilizing the updated data set is planned for the near future to compare between newer escapement estimation (backcast through historical data-sets) and an escapement goal based upon the same data. Punch card data used to estimate the recreational sport catch are not yet available for 2009; hence terminal run size estimates from this method are not available for this year. Significant area closures in addition of daily and seasonal bag restrictions are believed to have contributed substantially towards performance of the escapement goal in the Siuslaw basin during the 2009 return year. This stock is forecast to exceed escapement goal in 2010.

Commentary Coded-wire tagged fall-run Chinook salmon from the Umpqua River have indicated that they are harvested in PSC fisheries. Four years of USCTC funded research has allowed the calibration of the redd counts to derive a fish per redd expansion factor so that annual escapements estimates can be made. The average expansion factor from these studies is 3.69 fish per redd. The coefficient of variation of the expansion factor was found to be $14 \%$, which shows that the average expansion factor is a reliable statistic to use for annual estimates of escapement. The escapement estimate for 2009 was 3,014 based on redd count expansions. Indexes of Chinook salmon spawner abundance in the South Umpqua/Cow creek sub-basin were derived from aerial redd count surveys. The aerial surveys are funded by Douglas County and were conducted twice during the spawning season. Aerial redd counts were conducted on the lower 69 miles of the South Umpqua and the lower 60 miles on Cow Creek. These counts cover all mainstem spawning areas for fall Chinook salmon in the South Umpqua Basin. The South Umpqua is broken up into three reaches (Forks to Happy Valley, Happy Valley to Cow Creek, Cow Creek to Milo) and Cow Creek is considered one reach from the confluence with the Umpqua River to Galesville Dam.

The Coastal Chinook Research and Monitoring project was able to provide a calibration of redds to spawner escapement estimate based on the years 1998 through 2003 excluding 2002 when aerial flights were not conducted. The mean number of fish per redd estimated from these five years was 3.4 with a coefficient of variation of $17.8 \%$

Aerial surveys are conducted using a Bell Ranger 3 helicopter and flights are typically scheduled to encompass the peak spawning period. Two biologists simultaneously count redds for each reach using hand tally-counters. At the end of the reach, each biologists will record the number of redds identified, and counters reset for the next reach. The average of the two observers Chinook salmon redd count from reach will be determined for both flights. The index is defined as the sum of the peak counts for each reach between the two flights. Expansions are sometimes made to account for portions of reaches that were not completed due to visibility or mechanical problems.

Terminal run estimation is currently being conducted and will require some measure of data mining in order to reconstruct what the terminal catch has been historically. Preliminary indications are that the terminal catch of South Fork Umpqua Chinook salmon is insubstantial.

Commentary: Methods of estimation based on Mark-Recapture calibrated analysis indicate an adult Chinook salmon escapement for the Coquille basin of 15,653 spawners. Habitat-expansion based estimates indicate an escapement of 12,308 adult fish. Analysis funded by the CTC is underway that will provide information to designate Coquille Fall Chinook salmon as an escapement indicator stock for the Mid-Oregon Coast (MOC) Aggregate. Calibrated index of peak counts on standard surveys to a relatively precise mark \& and recapture abundance estimates has been selected as an efficient and cost effective means to measure spawner escapement of Chinook salmon for use in PST fisheries management.

The U.S. Chinook Technical Committee advises a Coefficient of Variation (CV) of $<30 \%$ should be achieved in order for an index be used as an estimator of abundance within the Chinook salmon management scheme. The CV between the qualifying calibration values computed from studies conducted from 2001 through 2004 for the Coquille River basin is $14 \%$, and the average index value of 0.00874 . This analysis include eight standard survey conducted annually on a regular basis. The calibration value is defined as the average peak count per mile of the eight standard surveys divided by the point value of the Petersen estimate. Peak count is defined as the largest sum of live Chinook salmon and carcasses observed on a particular day, per mile over a defined survey reach.

## 3 SENTINEL STOCKS PROGRAM

### 3.1 INTRODUCTION

During recent negotiations within the Pacific Salmon Commission to amend the current Chinook salmon regime under Chapter 3, Annex IV of the Pacific Salmon Treaty, it became apparent that the accuracy and precision of spawning escapement estimates for many important natural stocks of Chinook salmon may not be adequate to support the Treaty management process. Reliable estimates of spawning escapements for a large number of natural Chinook salmon stocks over time are critical to assessing and monitoring the status of the resource throughout the Treaty area, as well as to determining whether adjustments to particular fisheries are necessary and effective for achieving the long term conservation and production goals of the Treaty.

Recognizing the importance of better estimates of Chinook salmon spawning escapements, the Commission conceived the five-year Sentinel Stock Program (SSP) and included it as a specific requirement in the revised Chinook salmon regime (see Paragraph 3(a) of Chapter 3, Annex IV). The SSP is intended to focus on improving spawning escapement estimates for a select subset of important natural Chinook salmon stocks for which existing estimates are critical to fishery management decisions required by the Chinook salmon regime. Improving these estimates will bolster the scientific basis of the Chinook salmon regime, increase confidence in management decisions required under the new regime, and better inform the development of future regimes.

The goal of the Sentinel Stocks Program is to improve estimates of the spawning escapements for each of the included stocks to a level that meets or exceeds bilateral assessment accuracy and precision standards. Nine projects were funded by the SSP in 2009, the first year of the SSP. Summaries for each project are reported in Appendix C.

### 3.1.1 Oregon

### 3.1.1.1 Nehalem

The spawning escapement, 4070 (CV = 18\%) was estimated using mark-recapture methods. Returning fish were captured by using nets and weirs and then marked with opercular punches. Subsequent carcass surveys were used to recover marked and unmarked fish from the spawning grounds. Since there was no terminal sport fishery in 2009, no creel survey was necessary.

### 3.1.1.2 Siletz

This mark-recapture program relied on nets and weirs to capture returning fish in the lower river, which were then marked with opercular punches. Carcasses were examined for marks at the spawning grounds. A creel survey was also conducted to estimate removals of marked fish by the terminal sport fishery. The preliminary spawning escapement was estimated at 2,270 Chinook salmon (CV = 13\%).

### 3.1.2 Puget Sound

### 3.1.2.1 Snohomish

This study attempted to capture and mark live Chinook salmon using beach seines and eddy-set tangle nets and then subsequently recapture them as carcasses on all known spawning grounds or sample them at Sunset Falls, Wallace River Hatchery, and Tokul Creek Hatchery to estimate spawning escapement. Only 31 Chinook salmon were captured and 25 tagged, and only one was physically recaptured at Wallace Hatchery, making an estimate of spawner abundance using mark-recapture statistics impracticable.

### 3.1.2.2 Skagit

This SSP project was designed to evaluate the feasibility of using a fish trap in the lower Skagit River as a capture and tagging location for a basin-wide mark-recapture study. The fish trap caught zero Chinook salmon and no other fin-fish. The project demonstrated that it was not feasible to use the trap to capture sufficient Chinook salmon for a basin-wide mark-recapture study.

### 3.1.3 WCVI

### 3.1.3.1 Kaouk

A floating weir was installed to count fish returning to spawn and to facilitate a mark-recapture study with tag application below the weir and tag recovery above the weir. No fish were caught at the weir due, partially, to severe weather in September and tidal influence at the weir. Further, 13 Chinook salmon were radio tagged, however too few were detected subsequently to estimate spawning escapement using mark-resight methods.

### 3.1.3.2 Burman

This SSP project estimated spawning escapement (2,363 Chinook salmon; CV = 6\%) using mark-recapture methods. Returning fish were captured with beach seines in the lower river and then tagged and released. Carcasses were recovered upstream at the spawning grounds and examined for tags.

### 3.1.4 Fraser

### 3.1.4.1 South Thompson River

Spawning escapement to the South Thompson Age 0.3 aggregate was estimated using a combination of genetic, scale age, and CWT information collected from the Northern BC troll fishery and Albion (Fraser River) gillnet test fishery, along with CWT information collected at the Lower Shuswap River. A Bayesian estimation model was used to estimate escapement while considering uncertainty in these information sources. Differences in the spawning escapement estimates based on the Albion (169,000 Chinook salmon; CV = 6\%) and Northern BC troll fisheries ( 155,000 Chinook salmon; $C V=17 \%$ ) were minor and well within the variation due to sampling variability.

### 3.1.5 Northern BC

### 3.1.5.1 Skeena River

Escapement to the Skeena River, 79,838 Chinook salmon (CV = 17\%), was estimated from the genetic analysis of representative samples collected at the Tyee test fishery and the spawning abundance in the Kitsumkalum River. The SSP funded the genetic analysis of the test fishery samples in order to identify fish originating from the Kitsumkalum River, which was used to estimate the ratio of fish caught in the test fishery to the spawning grounds for the Kitsumakalum River. The total test fishery catch was expanded by that ratio.

### 3.1.5.2 Nass River

This SSP project was part of a larger basin-wide escapement program where Chinook salmon were captured and tagged at fishwheels in the lower Nass River and then recovered and examined for marks at upstream tributaries. The SSP funded the operation of a counting fence on the Kwinageese River where 28 marked fish were found among the 895 inspected. This sampling event essentially doubled the total number of tag recoveries for the mark-recapture program and improved the accuracy and precision of the total spawning escapement estimate of 26,864 Chinook salmon (CV = 13\%).

Troll, net, sport and total catches include catch of SEAK hatchery-origin fish; catches that count towards the all-gear ceiling (with hatchery add-on subtracted) are shown in the "treaty catch" column.
"-" = not applicable.
${ }^{1} 2003$ values reverted back to original values published in TCCHINOOK05-2.
${ }^{2}$ The value on top excludes District 108 Stikine catch above base levels. The value below includes it.
${ }^{3}$ Values in these years changed due to correction in the accounting of the TBR terminal exclusion.

${ }^{1}$ Since 1998, the catch accounting year for troll fisheries was set from October 1-September 30. To make comparisons to previous years more meaningful, the same catch accounting period was applied for years prior to 1998.
${ }^{2}$ freshwater catch included with tidal catch
NA=not available
${ }^{3}$ Troll and Net catches from 1996-2004 have been updated with data from the Catch Finalization Project
Net catch excludes jacks and small red-fleshed Chinook salmon.

Troll: Areas 21, 23-27, and 121-127; Net: Areas 21, and 23-27; Sport: Areas 23a, 23b, 24-27
${ }^{1}$ Since 1998, the catch accounting year for troll fisheries was set from October 1-September 30. The same catch accounting period was applied for years prior to 1998.
${ }^{2}$ Prior to 1992, catch was not reported as 'inside' or 'outside'. Therefore 'inside' catch for those years represents total tidal sport catch.
${ }^{3}$ Including 5,000 First Nations troll catch.
${ }^{4}$ Troll and Net catches from 1996-2004 have been updated with data from the Catch Finalization Project
${ }^{5}$ First Nations catch is mainly commercial catch 1996-2004 has been updated.

${ }^{1}$ The historical time series of catches in this year's report has changed from previous year's report. Catches after 1980 have been broken out into non-Treaty net and Treaty Indian due to the inability to separate commercial vs. non-commercial. Catches from 1975-1980 are consistent for sport and total with the later times series.

1/ Under the 2008 CRFMP, Upper Columbia Summer Chinook salmon are managed for a combined hatchery and natural tributary spawning escapement of 20,000. Snake River spring/summer Chinook salmon are managed separately.
/ This is the number of naturally spawning adult fish in the Lewis River. The terminal run given is the escapement plus the Lewis River sport catch of wild adults.
3/ In 2002, the escapement goal of 40,000 was agreed to by the CTC. The 2008-2017 US v OR Management Agreement includes a minimum management goal of 60,000 adults for Columbia River and Snake River upriver brights combined, including both hatchery and natural production for all areas above McNary Dam. The new agreement also includes 43,500 as the minimum Upriver Bright adult escapement, including Priest Rapids broodstock. The escapements listed are the McNary Dam count, minus Hanford sport and broodstock. The terminal run is the Columbia River mouth terminal run of Upriver Brights minus the Deschutes River fall Chinook salmon terminal run. 4/ 2004 escapement data updated by ODFW.
5/ The time series for escapement has been completely changed as run reconstruction methods were improved and reconstructed fro the entire time series.
$6 /$ Escapement was estimated for these years for the entire river using the methods shown in Sharma et. al. (2010). This was primarily done as there were no lower river redd-surveys conducted for these years and the Mark recapture method above Sherars needed to be expanded for the entire river.

Appendix B.6. Oregon Coastal escapements as estimated via traditional habitat expansion methods and terminal runs of PSC
Chinook Technical Committee wild Chinook salmon escapement indicator stocks.

## Appendix C. Sentinel Stocks Program in 2009.

The Sentinel Stocks Committee (SSC) met in Seattle during March 2009 to review and recommend projects for funding under the Sentinel Stocks Program (SSP). Fourteen proposals were reviewed and 10 were recommended for funding in 2009. The Pacific Salmon Commission approved funding for nine of the ten proposals. The proposals were chosen as per the approach outlined in the directive from the Commission to the SSC entitled Implementation Approach for the Chinook Sentinel Stocks Program, October, 2008 and the Sentinel Stocks Program Second Stage Proposal Evaluation, February, 2009. Recommended proposals represent stocks in all five regions specified in the directive (North Oregon Coast, Puget Sound, Fraser River, west coast of Vancouver Island, and northern British Columbia). The sentinel stocks recommended for study are of significant importance to the management of fisheries for Chinook salmon under the Pacific Salmon Treaty. Funded projects and requested budget amounts are summarized in Appendix Table C-1. Summaries of results from these funded projects are provided in the narratives below

Appendix Table C-1. Projects and funding levels for the Sentinel Stocks Program in 2009.

## Nehalem \& Siletz Chinook Salmon Escapement Assessments

The Siletz and Nehalem populations of fall Chinook salmon are part of the Northern Oregon Coast (NOC) aggregate. The Nehalem basin is located at the far north of the NOC aggregate, while the Siletz basin is located approximately mid-section within the NOC aggregate of stocks. The NOC stock aggregate is considered one of five "driver stocks" in Aggregate Abundance Based Management (AABM) fisheries and is of high importance in both AABM and Individual Stock Based Management (ISBM) fisheries. The NOC aggregate has historically been a highly productive and resilient stock complex. However recent failures to reach escapement goals in all three indicator stocks within the aggregate have prompted greater interest in quantifying the performance of this group. The 1995 to 2004 adult spawning escapement average in the Siletz River was 7,242 Chinook salmon. In the Nehalem River, the 1999 to 2008 adult spawning escapement average was 8,541 Chinook salmon.

## Methods to Estimate Escapement

In both basins, spawning escapement was estimated using standard mark-recapture methods. Adult fish were captured upon return to each basin using nets and weirs. Fish were marked using operculum punches, the location of which was varied to represent different time frames of freshwater entry. The second capture event(s) occurred on the spawning grounds. Pre-selected reaches were surveyed by foot or by boat and live fish, carcasses, and redds were counted. A creel survey was conducted in the Siletz basin. No creel survey was conducted in the Nehalem as the fishery was closed under emergency rule. Comparison to Historic Estimates
Historically, spawner escapement in Oregon coastal basins was derived using habitat-expansion methodology. Standard spawning ground surveys were conducted to record live and dead Chinook salmon counts. A peak count (largest daily sum of live and dead counts for a given survey location) was identified, and an index calculated (fish per mile). The index was expanded to total estimated available spawning habitat in each basin. Additional functions were used to adjust for observation and non-random bias. Department personnel have calculated estimates using these traditional methods while concurrently conducting mark-recapture experiments in the Siletz basin since 2005 and in the Nehalem basin from 2000 to 2003 and in 2009 (Appendix Table C-2).
Results Summary
A total of 235 adult Chinook salmon were marked in the Siletz River basin during the 2009 return year. A total of 465 adult carcasses were recovered on the spawning grounds; 46 of which were marked ( $>19 \%$ recovery rate). The percentile method was used to calculate the $95 \%$ confidence intervals from a 1,000 bootstrap samples. The interval lies between the $25^{\text {th }}$ lowest value and $25^{\text {th }}$ highest value of bootstrap population estimates. Chi square tests indicated a significant temporal bias with the mark - recapture experiment, thus the pooled Peterson technique was compared to a stratified Darroch estimate $(2,744)$ for an assessment of accuracy. The pooled Petersen is presented as an estimate of abundance, but further analysis may be warranted to determine which estimator may be best suited for use in the calibration analysis. The total escapement to the spawning ground was estimated to be 2,270 adult Chinook salmon, with a coefficient of variation (CV) of $13 \%$. This CV is within the CTC standard of $15 \%$.
In the Nehalem River basin for 2009, a total of 326 adult Chinook salmon were marked using four unique placements of operculum punches. A total of 546 qualifying carcasses were examined on the spawning grounds. Thirty-nine were marked for a mark recovery rate of almost $12 \%$. Given the low number of returns per stratum, low level of precision of the stratified estimator, and relative similarity of the stratified and pooled Peterson estimates (within 95\% CI of pooled estimator), the pooled Petersen estimator was selected to estimate the population size. The pooled Petersen estimate for the Nehalem basin was 5,332 adult fish with a CV of $17.7 \%$. The CV is slightly higher than the CTC standard of $15 \%$. This may be due to the fact that this was a new system for many staff and new survey areas and techniques were under investigation. It is anticipated that the CV in future years will decline as personnel become more familiar with the basin and sampling techniques improve with experience.
Calibration or Expansion Factors
Given future and current constraints around personnel and funding resources; this research has focused on identifying a spawning ground survey protocol using peak counts as the index to track fall Chinook salmon spawner abundance. Previous studies in the Siuslaw and Salmon Rivers correlating various survey indices to a mark-recapture derived escapement estimate, suggest that peak counts performed as the most consistent indicator of abundance when compared to other visual indices. Standard surveys located in the Siuslaw basin differ from those in these basins, in that all fall within the larger, mainstem habitat type, while all of the Siletz and some of the Nehalem standard surveys are located in smaller tributary habitats.

During low water years or during low abundance returns, the smaller tributary habitats are often not used and exhibit high spawner density variability.

Preliminary analysis of the potential standard surveys located on the mainstem Nehalem and the Siletz River basins have been conducted. Values presented as "calibration value" are defined as the "count" value divided by the Petersen mark-recapture estimate. The ideal conversion factor value would have an inter-annual CV of 0 , if it tracks perfectly with changes in spawner abundance (Appendix Table C-3). Variability in the inter-annual CV is likely underestimated as this descriptive statistic does not incorporate the precision of the population estimate used, nor does it incorporate the variability within the survey index.

## Future Escapement Estimates

The agency's intent is to identify a cost-effective spawning ground survey design where one or more of the measured metrics accurately and relatively precisely represent Chinook salmon spawner abundance for the basin. The current focus is to increase the proportion of mainstem habitat surveyed from previous years to increase the probability of identifying survey reaches where fish counts will consistently track the spawner estimate derived through the mark-recapture component of this study, regardless of run strength or water levels. The ODFW intends to survey these select mainstem or large tributary reaches annually throughout the duration of these studies. This analysis will require multiple years of statistically sound mark-recapture experiments before a complete assessment of survey results can be performed with an acceptable level of uncertainty.

Appendix Table C-2. Comparisons of Chinook salmon spawner escapement estimates between traditional, habitat expansion methods and mark and recapture techniques with associated coefficient of variation (CV)

## Snohomish Chinook Salmon Escapement Assessment

Spawner abundance of certain spring, summer, and fall Chinook salmon stocks in Puget Sound, including those in the Snohomish River system, have historically been estimated from counts of redds. Additionally, adult salmon abundances in the Snohomish Basin estimated at Sunset Falls, the Wallace River Hatchery, and the Tokul Creek Trout Hatchery, have been added to the estimated natural spawners to yield basin total spawner escapement.
This study attempted to capture and mark live Chinook salmon in the Snohomish River Basin using beach seines and eddy-set tangle nets, and to subsequently recapture them as carcasses on all known spawning grounds or sample them at Sunset Falls, Wallace River Hatchery, and Tokul Creek Hatchery to generate a statistically defensible spawner escapement estimate. Each fish was marked with two uniquely coded tags: an external Floy dart tag and an injected Passive Integrated Transponder (PIT) tag. Though initial plans also included oral insertion of a radio telemetry tag into a subset of fish, sample size was so low that every fish received a radio tag. In total, only 31 Chinook salmon were captured and 25 fish were tagged. Only one was physically recaptured at Wallace Hatchery, making an estimate of spawner abundance using mark-recapture statistics impracticable. Radio telemetry data showed that fish dispersed throughout the Snohomish basin from the tagging site on the mainstem Snohomish River and that movement was correlated with flow pulses. Although sample size was small, fish moved as individuals rather than groups and were never observed to hold in the same hole concurrently. Several non-adipose fin marked fish spawned in close proximity to the Wallace River Hatchery.

## Skagit River Chinook Salmon Capture Feasibility Assessment

The principle investigators did not submit an executive summary as specified and requested by the SSC and the CTC. Based upon information provided to the SSC in December 2009, no Chinook salmon were caught in the fish trap built and fished in the Skagit River.

## Kaouk Chinook Salmon Escapement Assessment

The WCVI Chinook salmon stock aggregate consists of production primarily from 27 spawning streams that are represented by six escapement indicator index streams identified in Attachments IV of the PST: Marble River (Area 27), Tahsish, Artlish, Kaouk (Area 25), Tahsis, and Burman Rivers (Area 25); and an eleven stream index including additional streams to those in Attachments IV. WCVI Chinook salmon are far north migrating and assumed ocean distributions are similar to the Robertson Creek Hatchery (RCH) Chinook salmon indicator stock. RCH coded wire tagged Chinook salmon are regularly recovered from sampling in the SEAK, NBC and WCVI AABM fisheries and from Central Coast and WCVI ISBM fisheries. Kaouk River Chinook salmon are not exposed to directed ISBM terminal commercial net, First Nations Economic Opportunity freshwater net fisheries (Canada Net), nor directed sport fisheries in the terminal area as are the RCH stock in Barkley Sound, so relative exploitation rates in the seaward fisheries are likely somewhat different than is the case for RCH Chinook salmon. No historic age data are available to assess maturation rates or other biological characteristics of the spawning population. A floating weir was built with a concrete fishway and an aluminum trap box to enumerate and sample escaping adult Chinook salmon. A secondary mark-recapture study was also planned using 60 radio tagged Chinook salmon. Due to severe weather in the month of September and the tidal influence at the weir site, Chinook salmon were not counted through the weir. The weir was topped a total of three times. An escapement estimate based on weir counts was not possible. The bulk of Chinook salmon passed over the weir during the September $18^{\text {th }}$ flood event, based on a swim survey conducted on the $24^{\text {th }}$. Since a weir based estimate was not produced, calculating an expansion factor was not possible. Therefore the only escapement estimate produced was based upon the normative swim based area-under-the-curve
(AUC) methodology. The AUC estimate for 2009 was 550 Chinook salmon, which is above the 15 -year average. Assessments from past escapement programs based on AUC estimates have resulted in annual escapement estimates that ranged from as low as 110 fish in 2000 to a high of 820 fish in 1998 with a 15year average (1995-2008)of 380 fish.

## Burman Chinook Salmon Escapement Assessment

The WCVI fall Chinook salmon stock aggregate is an important production group contributing to catches of Chinook salmon in Alaskan and Canadian Aggregate Abundance-Based Management fisheries and Canadian Individual Stock-Based Management fisheries. The stock group includes four Conservation Units, described under the Canadian Wild Salmon Policy, occupying the west coast of Vancouver Island (WCVI), British Columbia. Burman River Chinook salmon belong to the Nootka-Kyuquot Conservation Unit. The Burman River Chinook salmon population is an escapement indicator population described in the PST Chinook Attachments I-IV. Escapements to the Burman River are summed along with the estimated escapements to five other streams to produce a six-stream index representing WCVI escapement trends. The Burman escapement estimate is also summed in a second larger index that includes eight additional WCVI streams. Exploitation of the aggregate is assumed to be represented by the Robertson Creek Hatchery Coded-Wire Tag exploitation rate indicator stock. Low stock status in the stock group has prompted fishing restrictions in Canadian fisheries since 1995. More recently, conservation concerns for the WCVI stock group and other southern stocks prompted a $15 \%$ reduction in the Chinook salmon catch levels in southeast Alaskan fisheries as negotiated in the recent Pacific Salmon Treaty. Over the prior 10 year period (1999-2008), escapements to the Burman River averaged 841 adult Chinook salmon based upon area under-the-curve swim survey methodology.

Attempts to estimate Chinook salmon escapement with three separate 2-event mark-recapture experiments aimed at age-3 and older Chinook salmon were made. The abundance of Chinook salmon that returned in 2009 to the Burman River was estimated with an unconventional 2-event Petersen mark-recapture experiment: marking and recaptures of fish occurred concurrently over the spawning period. Chinook salmon were captured and marked using a beach seine in the lower river staging area below the counting sections; by beach seine and tangle net in river counting sections; and, by recovering carcasses. Biological samples and marks were also recovered from two hatchery brood collections. All Chinook salmon captured, with the exception of fish released unmarked during the hatchery brood collections, were marked with two individually numbered \#3 Kurl-lock tags attached to the opercula and a secondary mutilation mark. Fish were identified by gender, and post-orbital hypural length was measured. Scales were collected for ageing and otoliths were recovered from carcasses and hatchery brood collections to determine origin.
A total of 375 adult Chinook salmon (163 females and 212 males) were marked in the lower river. A total of 740 live adults ( 327 females and 368 males) were subsequently captured in the same location of which 149 ( 72 females and 77 males) were marked. The resulting pooled Petersen estimate of $\geq$ age- 3 and older Chinook salmon ( $>500 \mathrm{~mm}$ ) was 2,363 fish ( $\mathrm{SE}=136.9, \mathrm{CV}=5.8 \%$ ). The CV of the estimate met the data standard of $15 \%$. The stratified estimates of abundance were 1,444 ( $\mathrm{SE}=119.5, \mathrm{CV}=8.3 \%$ ) $>$ age $=3$ males and 933 ( $\mathrm{SE}=70.8, \mathrm{CV}=7.9 \%$ ) females. The estimate for age- 2 males ( $\leq 500 \mathrm{~mm}$ ) was 375 ( $\mathrm{SE}=$ 89.8 , $\mathrm{CV}=23.9 \%$ ) derived by marking 58 and recapturing 10 with marks among a catch of 69. Statistical tests for selectivity indicated the lower river samples were unbiased, and with the exception of a single age sample could be pooled. Bootstrapping with 1,000 samples of the mark-recapture data indicated a positive statistical bias of $2.4 \%$. The $95 \%$ confidence interval sample was $1,450-2,930$ fish. Selectivity
bias for gender and size were identified in the carcass survey data and near size bias was indicated in the live river recaptures where recapture rates were less than downstream.
The ratio of males to females was 1.23:1.00. The age structure for age-3 and older Chinook salmon was 32.3 \% age-3 fish, 31.2 \% age-4 fish, $33.3 \%$ age-5 fish, and $2.3 \%$ age- 6 fish. Age- 3 males were the most abundant component in the return followed by age- 5 fish that were largely females. Origin proportions estimated from thermal otolith marks indicated that $0.0707(\mathrm{SE}=0.0153)$ were naturally spawned and the remainder originated from hatcheries: 0.6396 ( $\mathrm{SE}=0.0286$ ) of the total were from the Burman River hatchery program; and, $0.2898(\mathrm{SE}=0.0270)$ had strayed from other hatcheries in the region.
The normal area-under-the curve index ( AUC $_{\text {index }}$ ) swim survey estimate for 2009 was $1,801>$ age- 3 fish. The expansion factor between the $\mathrm{AUC}_{\text {index }}$ estimate and the mark-recapture estimate was 1.31. The AUC index estimate was within the $95 \%$ confidence interval of the mark-recapture estimate. Hatchery brood collections removed 209 Chinook salmon that are included in the AUC index abundance estimate.

## South Thompson Chinook Salmon Escapement Assessment

A Bayesian model was developed to estimate the escapement of an aggregate salmon stock based on Genetic Stock Identification data and recoveries of coded wire tags (CWTs) from a hatchery indicator stock in distant fisheries and on the spawning grounds. The model was applied to data from 2009 for the South Thompson Age 0.3 Chinook Aggregate, a significant component of the Fraser early model stock used by the CTC. The expected escapements for the South Thompson aggregate, based on data from the Fraser River gillnet test fishery (Albion) and NBC troll fishery were 169,000 (CV=0.06) and 155,000 (CV $=0.17$ ), respectively. Differences in the two estimates were minor and well within variation due to sampling error. Age-specific estimates of escapement were relatively precise in cases where the uncertainty in the expanded number of CWT recoveries in the fisheries was low. The model was not able to reliably estimate escapement for age-5 fish, as no CWTs were recovered in either fishery. Increasing the number of CWT recoveries is essential to reduce uncertainty in age-specific escapement estimates. In support of this process CWT releases to the Lower Shuswap River indicator in 2009 were increased from 200,000 to 250,000 and to the Middle Shuswap River from zero to 150,000.
The Fraser River Chinook salmon Summer-Run Age 0.3 aggregate stock is a major contributor to ocean fisheries in Southeast Alaska (SEAK) and Northern British Columbia (NBC). Since 2002, this stock represented upwards of $30-40 \%$ of the NBC troll fishery catches. Good quality spawning ground estimates for this stock group are needed to develop accurate forecasts of the NBC and SEAK abundance indices to define allowable catch. However, the current visual survey methods are thought to underestimate spawner numbers because of poor counting conditions experienced during helicopter surveys in the South and lower Thompson rivers. Results from the Lower and Middle Shuswap escapement survey calibration programs indicate escapements can be underestimated by 20-65\% in the Fraser Summer-run Age 0.3 aggregate.
The Sentinel Stocks program provided $\$ 101,500$ CAN for this project in 2009 with the majority of funds directed to the increased tagging of hatchery releases in the South Thompson Aggregate and to the costs associated with increased sampling effort in the Lower Shuswap River mark-recapture program. The PST's Northern Endowment Fund contributed to the majority of the model development work with additional Sentinel Stock funds used to optimize it for the South Thompson aged 0.3 aggregate.

## Skeena Chinook Salmon Escapement Assessment

The number of Chinook salmon returning to the Skeena River in 2009 was estimated using the proportion of Kitsumkalum River fish measured from genetic samples collected at Tyee and the estimate of the Kitsumkalum Chinook salmon escapement from an independent mark-recapture project. The Skeena

River has the third largest aggregate of Chinook salmon spawning populations in British Columbia and is one of the escapement indicator stocks defined by the Pacific Salmon Treaty for North/Central British Columbia. Chinook salmon escapements to the Skeena River are represented by an index that includes approximately 20 populations surveyed annually using a variety of techniques. The Kitsumkalum River is the exploitation rate indicator stock for the Skeena Chinook salmon complex and spawning escapements have been estimated using a mark-recapture program since 1984. Fish counting weirs are present on the Babine, Sustut and Kitwanga Rivers but the Babine weir only counts part of the Babine population and the Sustut and Kitwanga populations are relatively small. Other escapement estimates that contribute to the index are based on visual observations from helicopter, fixed wing aircraft, boats and foot surveys. The index of Chinook salmon escapement to the Skeena aggregate has averaged 50,000 fish since 1984 (Appendix Table C-4). The Kitsumkalum indicator stock represents approximately $30 \%$ of the spawners in the escapement index. The Bear and Morice River populations have contributed $20 \%$ and $26 \%$ of the escapement index respectively since 1984.

Appendix Table C-4. Skeena Chinook salmon escapement index 1984 to 2009.

| Year | Skeena Escapement Index | Year | Skeena Escapement Index |
| :---: | :---: | :---: | :---: |
| 1984 | 35,864 | 1997 | 42,539 |
| 1985 | 52,407 | 1998 | 46,774 |
| 1986 | 59,719 | 1999 | 43,775 |
| 1987 | 60,948 | 2000 | 51,804 |
| 1988 | 68,307 | 2001 | 81,504 |
| 1989 | 57,192 | 2002 | 44,771 |
| 1990 | 55,541 | 2003 | 56,758 |
| 1991 | 52,792 | 2004 | 39,552 |
| 1992 | 67,118 | 2005 | 29,496 |
| 1993 | 68,286 | 2006 | 36,682 |
| 1994 | 22,611 | 2007 | 37,054 |
| 1995 | 34,390 | 2008 | 34,615 |
| 1996 | 73,684 | 2009 | 38,597 |

Skeena Chinook salmon are encountered in the PST Aggregate Abundance Based Management (AABM) fisheries in Southeast Alaska (SEAK all gear) and Northern British Columbia (NBC Troll and Haida Gwaii (QCI) Sport). They also contribute to the Individual Stock Based Management (ISBM) fisheries in Northern British Columbia including gillnet, tidal sport, non-tidal sport, tidal First Nations' (FN) and nontidal FN fisheries. Skeena Chinook salmon are north migrating so they do not contribute to the West Coast Vancouver Island (WCVI) AABM fisheries nor do they contribute appreciably to ISBM fisheries south of the Skeena River.
The preliminary estimate of large Chinook salmon returning to the Skeena River in 2009 as measured at Tyee was 79,838 fish with a standard deviation of 13,601 fish (coefficient of variation $=17 \%$ ). The proportion of Kitsumkalum fish in samples of 1,155 Chinook salmon caught at Tyee was $13.4 \%$ with a standard deviation of $1.4 \%$. The escapement of large Chinook salmon to the Kitsumkalum River was estimated from an independent mark-recapture estimate at 10,703 fish with a standard deviation of 1,424 fish.
The 2009 data were compared with genetic analyses completed for Chinook salmon samples collected at Tyee in 2000, 2001 and 2003 (Appendix Table C-5). Preliminary estimates for the Chinook salmon return
to the Skeena River had coefficients of variation between $15.2 \%$ and $17.2 \%$. Improvements were expected in 2009 as the sample sizes were increased at Tyee and the genetic baselines were improved. However, these improvements were not realized due to broader variance around the 2009 mark-recapture estimate of Kitsumkalum River Chinook salmon escapement.

Appendix Table C-5: Skeena Chinook salmon escapement past Tyee from the proportion of Kitsumkalum Chinook salmon identified in the Tyee Test Fishery compared with the index.

| Year | Kalum Esc. <br> Mark- <br> Recapture | CV <br> Kalum Esc. | No. <br> Tyee DNA | \% Kalum <br> in Tyee <br> DNA | CV Kalum in Tyee DNA | Total Skeena Esc. from DNA | CV <br> Skeena <br> Esc. Est. | Skeena Esc. Index |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 14,722 | 8.2\% | 775 | 15.6\% | 12.8\% | 94,668 | 15.2\% | 51,804 |
| 2001 | 23,839 | 9.5\% | 569 | 19.7\% | 12.9\% | 120,803 | 16.1\% | 81,504 |
| 2003 | 23,608 | 11.0\% | 468 | 22.3\% | 13.2\% | 105,857 | 17.2\% | 56,758 |
| 2009 | 10,703 | 13.3\% | 1155 | 13.4\% | 10.6\% | 79,838 | 17.0\% | 38,597 |

Kalum = Kitsumkalum, No. = sample size, CV = coefficient of variation, Esc. = escapement, and Est. = estimate.
An objective for the project was to provide an escapement estimate for Skeena River Chinook salmon with a CV of less than $15 \%$. While the project failed to meet these criteria in 2009, the preliminary estimates represent an improvement over existing indices since it provides an estimate of variance. Variance estimates cannot be produced for the escapement indices of Skeena Chinook salmon because of the combination of different escapement techniques involved. Accurate determination of spawning escapements will require estimates of fishery removals upstream of Tyee and stock identification for fisheries between Tyee and the Kitsumkalum River to determine if Kitsumkalum fish suffer different fishing mortalities than other Skeena components.
The Sentinel Stocks program provided \$29,300 CAN for this project in 2009. This represented relatively frugal funding to estimate the Chinook salmon return to the Skeena River aggregate. The results are preliminary and will be revised after improvements to the Skeena genetic baselines are incorporated.

## Nass Chinook Salmon Escapement Assessment

The Upper Nass River Chinook Aggregate salmon stock forms one of the existing CTC wild Chinook salmon indicator stocks. This is a large stock group that has averaged 22,000 spawners per annum (44,000 total run) over the last decade and includes 16 separate populations including the Tseax River and all other populations that spawn within the Nass watershed upstream of the confluence of the Nass and the Tseax River. The Upper Nass River Chinook salmon Aggregate is important relative to the overall coastwide Chinook salmon resource. It represents a very stable proportion of the Chinook salmon stocks taken in northern BC and Alaskan fisheries. Upper Nass River Chinook salmon stocks contribute to the Aggregate Abundance Based Management (AABM) fisheries in Southeast Alaska (all gear types), Queen Charlotte Island recreational, tidal gill net, tidal sport, tidal First Nations, freshwater sport, and freshwater First Nation fisheries in Northern British Columbia. The Upper Nass River Chinook salmon Aggregate is a completely natural population with no history of enhancement and likely very little, if any, straying from other enhanced systems such as from the Kincolith or Kitsumkalum rivers.

Since 1994, mark recapture estimates of the Upper Nass River Chinook salmon Aggregate have been derived by marking Chinook salmon with operculum tags at fishwheels on the mainstem Nass River near the Nisga'a village of Gitwinksihlkw and recovering/examining live Chinook salmon for marks at the Meziadin fishway and Chinook salmon carcasses at other Upper Nass River tributary locations. Carcass
recovery locations have varied over the years but have been predominantly conducted in the Damdochax and Kwinageese rivers. Effort has been focused on these two systems as they were found to be significantly contributing stocks to the Upper Nass River Chinook salmon Aggregate population (~30\%) based on stock composition results from radio-telemetry studies conducted in 1992 and 1993. Carcass recoveries have also been attempted on other systems such as Cranberry, Snowbank, Tiegen, and Oweegee; but these have not resulted in adequate recoveries (i.e., $<5$ tags recovered) for generating reliable mark-recapture estimates or to justify the survey effort expended. Upper Nass River Chinook salmon Aggregate mark recapture estimates have achieved coefficients of variation (CV) less than or equal to $15 \%$ in 9 of 15 (60\%) years since 1994 with the main factor determining CV being the number of marked Chinook salmon recovered or examined at terminal spawning areas in the Upper Nass River watershed. Recoveries of marked Chinook salmon at Meziadin fishway alone are not sufficient to generate sufficiently reliable mark recapture estimates for the Upper Nass River Chinook salmon Aggregate; hence, additional recovery efforts on other tributaries are required each year to achieve a $15 \%$ or lower CV.

In 2009, a mark-recapture experiment was conducted to estimate the abundance of Upper Nass River Chinook salmon Aggregate adult salmon returning to the Nass River. The mark-recapture study was designed to meet or exceed the data standard of a $15 \%$ or lower CV estimate and identify repeatable procedures for future estimates. Adult Chinook salmon were captured with two fishwheels operated on the lower Nass River near the village of Gitwinksihlkw from 1 June to 12 September and fish were individually marked with aluminum "chick-wing" tags applied to the left operculum. A total of 1,213 adult Chinook salmon were tagged and 1,692 fish were examined at upstream tributaries (of which 57 had been previously tagged). After accounting for tags removed by in-river fisheries and other tag associated losses, the adult abundance above Grease Harbour of medium-sized Chinook salmon (500-754 mm, tip of nose to fork of tail) was estimated to be 7,568 fish ( $\mathrm{SE}=2,477$; $\mathrm{CV}=35.5 \%$ ) and abundance for large-sized ( $>754 \mathrm{~mm}$ ) Chinook salmon was estimated to be 19,297 fish (SE=2629; CV=14.0\%). Although mark rates were similar between medium- and large-sized Chinook salmon (3.2\% vs. 3.4\%, respectively), length distributions of Chinook salmon released with marks were significantly different than length distributions of adult Chinook salmon examined at the spawning grounds for marks (KolmogorovSmirnov test, Dmax $=0.112, \mathrm{p}<0.001$ ). As a result of this size selectivity, these separate mark-recapture estimates for medium and large-sized Chinook salmon were summed giving a total estimated abundance above Grease Harbour for adult Chinook salmon returning to the Upper Nass River of 26,864 (SE=5,106; $\mathrm{CV}=13.1 \%$ ). This estimate was $2.1 \%$ smaller ( $\sim 573$ fish) than an estimate derived by pooling all size classes into a single mark-recapture estimate. Combining the in-river harvests (638) and escapement between Gitwinksihlkw and Grease Harbour $(1,320)$ yielded an estimate of the total return of adult Chinook salmon to the Gitwinksihlkw fishwheels in 2009 of 31,289. The net escapement (spawners) estimate of adult Chinook salmon returning to the Upper Nass River in 2009 was 27,546 fish. A total of 726 Chinook salmon caught at the Gitwinksihlkw fishwheels were successfully aged; the most abundant age was five year olds ( $67 \%$; all age 1.3), followed by four year olds ( $26 \%$; age $1.2=23.8 \%$ and age $0.3=2.2 \%$ ), six year olds ( $5.4 \%$; age $1.4=5.2 \%$ and age $2.3=0.2 \%$ ) and three year olds ( $1.6 \%$; age $0.2=1.0 \%$ and age $1.1=0.6 \%$ ). The 2009 mark-recapture estimate for Upper Nass River Chinook Aggregate adult salmon achieved the data standard of $15 \%$ CV by mounting sufficient tag-recovery efforts to recover enough mark recoveries from the spawning grounds. The provision of $\$ 63,000$ from the PSC was significant in allowing this additional survey effort. Initial recommendations for the future to consistently achieve the data standard and eliminate any spatial biases in tag recovery efforts would be to operate a third tagging fishwheel at Gitwinksihlkw to increase the mark rates of all size groups, continue
tag recovery operations at Meziadin Fishway and the Kwinageese weir, and conduct carcass ground surveys at Damdochax Creek.

[^0]:    ${ }^{1}$ Since 1998, the catch accounting year for troll fisheries was set from October 1-September 30. To make comparisons to previous years more meaningful, the same catch accounting period was applied for years prior to 1998.
    ${ }^{2}$ Estimate of lower Skeena River sport catch only. Note that Troll (Areas 1-5) and Tidal Sport (Areas 1, 2E, 2W) are the components of the NBC AABM fishery. Net catch excludes jacks and small red-fleshed Chinook salmon.
    ${ }^{3}$ Troll and Net catches from 1996-2004 have been updated with data from the Catch Finalization Project.

[^1]:    ${ }^{\text {a }}$ A weir is used on the Situk River to estimate escapement. In 2010 a high water event during the peak of the run disabled the weir for 3 days and the 2010 estimate is a partial count.
    ${ }^{\mathrm{b}}$ Escapement is germane to fish age 2-ocean and older.

[^2]:    GW refers to Gitwinksihlkw, the location of the lower fish wheels on the Nass River used to capture Chinook salmon for the mark-recapture estimate.
    ${ }^{2}$ The Docee River was dropped as an escapement indicator due to an inability to obtain reliable escapement estimates.

[^3]:    *Additional analyses required to assess the influence of potential biases on the accuracy of the estimate.
