## EXECUTIVE SUMMARY

The June 30, 1999 Pacific Salmon Treaty (PST) Annex and the Related Agreement (Agreement) substantially changed the objectives and structure of the Pacific Salmon Commission’s (PSC) Chinook salmon fisheries and assessment of Chinook salmon stocks. The 1999 Agreement replaced the previous ceiling and pass-through fisheries with Aggregate Abundance Based Management (AABM) and Individual Stock Based Management (ISBM) fisheries. The 2008 Agreement updated and refined several aspects of the 1999 Agreement while continuing with the approach of abundance based management of PSC Chinook fisheries.

This report summarizes the 2010 fishery catches by region, provides available estimates of incidental mortality (IM) by fishery and provides limited commentary on fishery catches where needed. Landed catch is reported in the appendices for each geographic area covered under the PST. An assessment of escapement for stocks with Chinook Technical Committee (CTC) accepted goals is included, and escapement data through 2010 are provided for all escapement indicator stocks.
The escapements of 50 naturally spawning escapement indicator stocks are reviewed annually, along with the results from the Sentinel Stocks Program (SSP). Biologically-based escapement goals have been accepted by the CTC for 25 of the 50 escapement indicator stocks/stock aggregates. For 12 of these, the escapement goal is defined as a range; for the remaining 13, the escapement goal is the point estimate of $\mathrm{S}_{\mathrm{MSY}}$ (escapement producing maximum sustained yield). In 2010, the percentage of stocks meeting goal or goal ranges was $80 \%$, the highest percentage observed since 2005, indicating an improvement in stock status over the past few years. Of the five stocks below goal, one stock (Hoh Spring/Summer) was within $15 \%$ of the target goal. Four stocks were more than $15 \%$ below goal: Situk, Cowichan, Queets Spring/Summer, and Nehalem. Data for stocks without accepted goals are presented to illustrate trends in escapement. The CTC will continue to review escapement goals, as they are provided to the committee.
The CTC retrospectively evaluated the performance of the stock groups and the criteria for initiating additional management action in regards to Paragraph 13c, based upon observed escapements and exploitation rates through 2010 and stock forecasts for 2011. No stock groups listed in Attachment I-III met the criteria for triggering additional management action. However, only five of the 10 different stock groups in Attachments I-III have stocks with agreed management objectives that can be evaluated for triggering additional management action, and only six of these stocks had forecasts available for 2011. The CTC has identified a need to develop management objectives and forecast capabilities for more of the stocks included in Attachments I-III to improve the efficacy of Paragraph 13.

## 1 CHINOOK SALMON CATCH

The Agreement substantially changed the objectives and structure of the PSC Chinook salmon fisheries. The 1999 Agreement eliminated the previous ceiling and pass-through fisheries and replaced them with AABM and ISBM fisheries. The 2008 Agreement defines catch limits for AABM fisheries while ISBM fisheries are limited by adult equivalent (AEQ) mortality rates. Chinook salmon catches for the AABM fisheries in 2010 are summarized in Table 1.1-Table 1.4. Historical catches for PSC Chinook salmon fisheries are given in Appendices A.1-A.14.

Starting with the report CTC (2004a), the CTC included estimates of incidental mortalities associated with landed catch for each component of each AABM fishery and most ISBM fisheries (CTC 2004b). Limited commentary on both AABM and ISBM fisheries is also provided.

### 1.1 Review of Aggregate Abundance Based Management Fisheries

AABM fisheries for Chinook salmon are managed to achieve a target catch corresponding to a target harvest rate index and each year's abundance index (AI) in Table 1 of the Agreement. AABM fisheries are mixed stock salmon fisheries that intercept and harvest migratory Chinook salmon from many stocks. The AABM fisheries (Annex IV, Chapter 3, paragraph 2) are:

1) Southeast Alaska (SEAK) All Gear,
2) Northern BC (NBC) Troll and Queen Charlotte Islands (QCI) sport, and
3) West Coast Vancouver Island (WCVI) Troll and Outside Sport.

Catches for these three fisheries are reported in Table 1.1.

Table 1.1 Annual catches and hatchery add-ons for the Aggregate Abundance Based Management fisheries, in thousands of Chinook salmon. The treaty catches do not include the add-on or exclusions (see Section 1.1.1 and Appendix A.1). Notation is T for Troll, N for Net and S for Sport.

| Year | Southeast Alaska (T, N, S) |  |  | Northern British Columbia (T), Queen Charlotte Islands (S) Treaty Catch |  | West Coast Vancouver Island (T, S) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Treaty Catch |  | Hatchery <br> Add-on |  |  |  | Catch |
|  | $\text { Limit }^{1}$ | Observed |  | $\text { Limit }^{1}$ | Observed ${ }^{2}$ | $\text { Limit }^{1}$ | Observed ${ }^{2}$ |
| 1999 | 184.2 | 198.8 | 47.7 | 126.1 | 86.7 | 107.0 | 36.4 |
| 2000 | 178.5 | 186.5 | 74.3 | 123.5 | 31.9 | 86.2 | 101.4 |
| 2001 | 250.3 | 186.9 | 77.3 | 158.9 | 43.5 | 145.5 | 117.7 |
| 2002 | 371.9 | 357.1 | 68.2 | 237.8 | 150.1 | 196.8 | 165.0 |
| 2003 | 439.6 | 380.2 | 57.2 | 277.2 | 191.7 | 268.9 | 175.8 |
| 2004 | 418.3 | 417.0 | 76.0 | 267.0 | 241.5 | 209.6 | 216.6 |
| 2005 | 387.4 | $390.5^{4}$ | 65.3 | 240.7 | 243.6 | 179.7 | 202.7 |
| 2006 | 354.5 | $362.4^{4}$ | 49.1 | 200.0 | 216.0 | 145.5 | 146.9 |
| 2007 | 329.4 | $328.5^{4}$ | 69.6 | 143.0 | 144.2 | 121.9 | 139.2 |
| 2008 | 152.9 | $173.0^{4}$ | 68.2 | 120.9 | 95.6 | 136.9 | 143.8 |
| $2009^{3}$ | 176.0 | $230.4^{4}$ | 65.2 | 139.1 | 109.5 | 91.3 | 124.6 |
| 2010 | 221.8 | 231.6 | 55.8 | 152.1 | 136.6 | 143.7 | 136.8 |
| 2011 | 294.8 |  |  | 182.4 |  | 196.8 |  |

${ }^{1}$ Allowable treaty catches correspond to the post season abundance indices for 1999-2010 and the preseason abundance indices for 2011.
${ }^{2}$ 1999-2004 Northern British Columbia and West Coast Vancouver Island observed catch changed with data from the Catch Finalization project.
${ }^{3} 2009$ was the beginning of the 2008 Agreement.
${ }^{4}$ Values updated to reflect removal of Andrew Creek Chinook from the terminal exclusion and to include traditional troll Chinook caught in D108 in the terminal exclusion calculation during years with a directed fishery.

### 1.1.1 Southeast Alaska Fisheries

The SEAK Chinook salmon fishery has been managed to achieve the annual all-gear PSC allowable catch (AC) through a plan established by the Alaska Board of Fisheries. Once the allgear AC is determined from the preseason AI each spring, this plan establishes gear quotas for the troll, net, and sport fisheries. The allocation plan reserves $4.3 \%$ of the total PSC catch for purse seine, $2.9 \%$ for drift gillnet and 1,000 fish for set gillnet fisheries. After the net quotas are subtracted, $80 \%$ of the remainder is reserved for troll gear and $20 \%$ for the sport fishery. The sport fishery is managed in season with bag-limits and other constraints. Regulatory history and maps for each SEAK fishery are described detailed in CTC (2004b).
In addition, the SEAK fisheries were managed for:

1) An Alaska hatchery add-on estimated from CWT sampling. The add-on is the total estimated Alaskan hatchery harvest, minus 5,000 base-period Alaskan hatchery harvest, and minus one-half of the $90 \%$ Confidence Interval (CI) for the total Alaskan hatchery harvest.
2) An exclusion of wild Chinook salmon originating from the Situk, Stikine and Taku Rivers, when appropriate.
3) Compliance with provisions established by the National Marine Fisheries Service in accordance with the U.S. Endangered Species Act (ESA).
4) Consistency with the provisions of the PST as required by the Salmon Fishery Management Plan of the North Pacific Fishery Management Council that was established by the U.S. Magnuson-Stevens Act.

The SEAK 2010 pre-season AI of 1.35 allowed an all-gear catch of 221,800 Chinook salmon. The preliminary all gear catch in 2010 was 287,528 with a PST catch of 231,591, an Alaska hatchery add-on of 55,816 , and a terminal exclusion catch of 121. Historical SEAK Chinook salmon catch numbers for 1975-2010 are included in Appendix A.1.

### 1.1.1.1 Troll Fisheries Harvest

The troll fishery accounting year began with the start of the winter fishery on October 11, 2009 and ended the following September, 2010. The winter troll fishery continues until 45,000 Chinook salmon are caught or through April 30, whichever is earlier (Lynch and Skannes 2009). In 2010, the harvest in the winter fishery was less than 45,000 and the winter troll fishery was open through April 30. The spring fishery was managed so that each fishing area would not exceed a predetermined number of non-Alaskan Chinook salmon, based on the Alaska hatchery percentage in each of the areas (Lynch and Skannes 2010a). The first summer fishery opening began on July 1 and was managed to harvest $70 \%$ of the remaining troll gear Chinook salmon quota based on the pre-season AI (Lynch and Skannes 2010b). After the first 70\% of the summer quota was harvested, the areas of high Chinook salmon abundance were closed and troll fishing effort was directed primarily at coho salmon. A second summer Chinook salmon retention period to harvest the remaining troll quota began on August 15, after necessary management actions for coho salmon were determined. In recent years, a small but increasing portion of the troll fleet has targeted chum salmon from mid-June through mid-August, resulting in a slight decrease in effort directed at Chinook and coho salmon.

In 2010, the troll fishery harvested 195,494 Chinook salmon, which included 21,684 Alaska hatchery fish for an Alaska hatchery add-on of 17,686, resulting in a total of 177,808 PST fish (Table 1.2). The winter fishery harvested 42,536 fish, of which 5,358 were from Alaska hatcheries and 38,205 were PST fish. The spring fishery harvested a total of 29,739, of which 11,969 were Alaska hatchery fish and 19,907 were PST fish. The total summer harvest was 123,219, of which 4,357 were from Alaska hatcheries and 119,697 were PST fish.

### 1.1.1.2 Net Fisheries Harvest

There are three types of commercial net fisheries conducted in SEAK, including purse seine, drift gillnet and set gillnet. The purse seine fishery is managed to harvest no more than $4.3 \%$ of the all-gear PST Chinook salmon quota and is open from mid-June through early fall. The purse seine management plan had the following provisions in 2010 (Davidson et al. 2010a):

1. Chinook salmon $>28$ " may not be retained
2. Chinook salmon $>21$ " and $<28$ " may be harvested but not sold
3. Chinook salmon below 21 " may be retained and sold at all times.

The drift gillnet fishery is managed to catch no more than $2.9 \%$ of the PST all-gear quota and does not usually open until late June, unless fisheries are implemented to target Chinook salmon bound for the Taku and Stikine Rivers (Davidson et al. 2010b). Directed fisheries were in place in 2010 for Taku River Chinook salmon, but did not occur for the Stikine River.

The set gillnet fishery is managed to harvest no more than 1,000 PST Chinook salmon, a limit which is based on historic catch, and is open during the late spring and summer in the Yakutat area.

The 2010 total net harvest was 33,531 Chinook salmon (Table 1.2) with 25,480 Alaska hatchery fish. There was an Alaska hatchery add-on of 24,032, resulting in a PST catch of 9,499. The PST catch by gear type was 501 Chinook salmon for set gillnet, 6,073 for drift gillnet and 2,925 for purse seine.

### 1.1.1.3 Sport Fishery Harvest

Sport harvests are monitored in season by creel surveys throughout the region, and sampling programs are in place to recover coded-wire tagged Chinook salmon and coho salmon. The number of Alaska hatchery fish harvested is estimated from the CWTs collected by the creel program. Final sport harvest estimates are computed from a mail out survey and are available one year after the fishery occurs. In 2010, regulations for the sport fishery had a two fish daily bag limit for all residents. Non-resident anglers had a one fish daily and a three fish annual limit. The minimum size limit of 28 " in total length was in effect for both resident and non-resident anglers throughout the season. In "terminal" areas near hatchery release sites, however, bag and size limit regulations were liberalized to provide for increased harvests of returning Alaska hatchery Chinook salmon. The total Chinook salmon harvest in 2010 was 58,503 with an estimate of 16,335 Alaska hatchery fish (Table 1.2). There was an Alaska hatchery add-on of 14,098 fish, resulting in a PST harvest of 44,284 Chinook salmon.

Table $1.2 \quad$ Harvest of Chinook salmon in Southeast Alaska by gear type in 2010.

| Gear | Total <br> Catch | Alaskan <br> Hatchery <br> Catch | Alaskan <br> Hatchery <br> Add-on | Terminal <br> Exclusion Catch ${ }^{1}$ | Treaty Catch |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Troll |  |  |  |  |  |
| Winter | 42,536 | 5,358 | 4,331 | 0 | 38,205 |
| Spring | 29,739 | 11,969 | 9,832 | 0 | 19,907 |
| Summer | 123,219 | 4,357 | 3,522 | 0 | 119,697 |
| Troll subtotal | 195,494 | 21,684 | 17,686 | 0 | 177,808 |
|  |  |  |  |  |  |
| Sport | 58,503 | 16,335 | 14,098 | 121 | 44,284 |
|  |  |  |  |  |  |
| Net |  |  |  |  |  |
| Set Net | 501 | 0 | 0 | 0 | 501 |
| Drift gillnet | 17,154 | 12,059 | 11,081 | 0 | 6,073 |
| Seine | 15,876 | 13,421 | 12,951 | 0 | 2,925 |
| Net subtotal | 33,531 | 25,480 | 24,032 | 0 | 9,499 |
|  |  |  |  |  |  |
| Total | 287,528 | 63,499 | 55,816 | 121 | 231,591 |

${ }^{1}$ Terminal exclusion catch is a result of the harvest sharing arrangement on the Taku and Stikine Rivers.

### 1.1.2 British Columbia Fisheries

Under the 1999 PST Agreement, AABM regimes were implemented to constrain catch. This agreement extended through 2008 and was renewed in the 2008 PST Agreement to 2018. The NBC AABM fishery includes NBC troll catch in Statistical Areas 1-5 and QCI sport catch in Statistical Areas 1 and 2. The total NBC AABM catch in 2010 was 136,613 . The WCVI AABM fishery includes the WCVI troll and a portion of the WCVI sport fishery (defined below). The total WCVI AABM catch in 2010 was 139,047 (Table 1.3). Troll catches from 1996-2004 have been updated with data from DFO (2009).
Table $1.3 \quad$ Summary of landed catch by gear for Canadian Aggregate Abundance Based Management (AABM) fisheries in 2010.

| AABM Fishery | Troll | Sport | Total |
| :--- | :---: | :---: | :---: |
| Northern British Columbia | 90,213 | 46,400 | 136,613 |
| West Coast Vancouver Island | 84,123 | 54,924 | 139,047 |

1.1.2.1 Northern British Columbia Troll Fishery Harvest

The Northern British Columbia (NBC) troll fishery landed 90,213 Chinook salmon in 2010. The NBC troll fishery was opened for Chinook salmon fishing from 15 June to 8 August. The entire 2010 NBC Troll fishery was conducted under a system of individual transferable quotas. A total
of 284 vessels were licensed but harvest was conducted by 147 vessels, as much of the quota was transferred. Barbless hooks and revival boxes were mandatory in the troll fishery and the minimum size limit was 67 cm . No troll test fisheries were conducted in 2010. A ribbon boundary around Langara Island and from Skonun Point to Cape Knox on Graham Island excluded the commercial troll fishery from areas within one nautical mile of the shore for the duration of the fishery.

### 1.1.2.2 Northern British Columbia and Central British Columbia Sport Fishery Harvest

Tidal sport fisheries in NBC and Central British Columbia (CBC), marine Statistical Areas 1-11, are managed under one set of regulations ( 45 cm minimum size limit; two Chinook salmon per day and four in possession; annual bag limit of 30). During the decade up to 2008, sport fisheries in the marine areas of NBC and CBC expanded substantially. Management of these marine sport fisheries now recognizes two regions: QCI, and the coastal mainland. Only the QCI sport catch is included in the AABM totals. Since 1995, catches in the QCI sport fisheries have been estimated by creel surveys, lodge logbook programs and independent observations by Canadian Department of Fisheries and Oceans (CDFO) staff. Catch for this fishery in 2010 was 46,400 Chinook salmon. The total NBC AABM catch (troll plus sport) between October 1, 2009 and September 30, 2010 was 136,613 Chinook salmon (Table 1.3).

### 1.1.2.3 West Coast Vancouver Island Aggregate Abundance Based Management

Under the 2008 PST Agreement, the WCVI AABM fishery includes the WCVI troll and the outside WCVI sport fishery (defined below). The total AABM landed catch in the commercial troll, outside tidal sport, and First Nations (FN) troll in 2010 was 139,047 Chinook salmon (Table 1.3).

### 1.1.2.3.1 West Coast Vancouver Island Troll Fishery Harvest

The AABM troll catch includes the commercial and FN troll caught Chinook salmon in Statistical Areas 21, 23-27, and 121-127. In the 2010 season (October 1, 2009-September 30, 2010), the WCVI troll fishing opportunities were consistent with a CDFO commitment to evaluate winter fisheries as a means to improve the economic base for the fleet and local communities while increasing flexibility in harvest opportunities and reducing the harvest rates on stocks encountered in summer fisheries (Table 1.4). Troll fishery openings were shaped by conservation concerns for Fraser River Spring run Age 1.2 and Fraser River Spring run Age 1.3, WCVI and Lower Strait of Georgia (LGS) Chinook salmon and interior Fraser River coho salmon.

To reduce impacts on early spring-run Fraser and LGS Chinook salmon, Southwest Vancouver Island (SWVI) areas 123-124 were closed from March 1 to late April. In addition, fisheries from late April to mid-June were managed to monthly effort quotas rather than catch quotas. To reduce impacts on interior coho, coho non-retention remained in effect for the spring/summer period, Fraser coho encounter rates were monitored, commercial fisheries were closed from midJune through July, and plugs were used to avoid impacts on coho in August and early September fisheries. To reduce impacts on WCVI Chinook, near shore area closures were in effect from August through mid-September. To reduce impacts on LGS Chinook salmon, harvest levels were reduced during the spring period when recent impacts were highest. This measure also provides some benefits to spring run U.S. Chinook salmon stocks when the mature run is abundant on the WCVI. Statistical Area 121 (Swiftsure Bank) remained closed in 2010. Selective fishing
practices were mandatory, including single barbless hooks and "revival tanks" for resuscitating coho salmon prior to release. The minimum size limits for commercial troll for all periods was 55 cm (fork length).
The 2010 commercial Area G troll anticipated harvest level was 83,700 Chinook salmon between October 1, 2009 and September 30, 2010.The actual catch for 2010 commercial troll fisheries was 79,123 Chinook salmon (Table 1.4). The April catch was $10 \%$ of the anticipated total catch at 8,553 Chinook salmon. May Chinook salmon catch in 2010 was 31,296 (37\% of the total allowable catch (TAC)). The WCVI FN caught an estimated 5,000 Chinook salmon in 2010. Therefore, the total WCVI AABM troll catch for 2010 was 84,123 with 375 legal and 4,892 sublegal Chinook salmon releases (not including releases from the WCVI FN troll fisheries, which are currently unknown).

The catches for 2010 commercial troll fisheries between October 1, 2009 and September 30, 2010 were 79,123 Chinook salmon (Table 1.4). The April catch was 18,553 fish ( $10 \%$ of the TAC) and the May catch was 31,296 (37\% of the TAC).
Table $1.4 \quad$ Fishing periods and Chinook salmon harvested and released during the 2010 catch year in the West Coast Vancouver Island commercial troll fishery.

${ }^{1}$ West Coast Vancouver Island troll fisheries were generally closed from mid-June to late August to avoid encounters of interior Fraser River and Thompson River coho and West Coast Vancouver Island Chinook salmon. ${ }^{2}$ DNA sampling of sublegal Chinook salmon by Area G.

### 1.1.2.3.2 West Coast Vancouver Island Sport Fishery Harvest

The AABM sport fishery includes all catch in northwest WCVI (Areas 25-27, 125-127; Figure 1) between October 16 through June 30, and the catch outside of one nautical mile offshore from July 1 through October 15, plus all the catch in southwest WCVI (Areas 21-24) from October 16
through July 31, and outside one nautical mile offshore from August 1 to October 15. Catch inside the surf line and outside the AABM periods specified above is included in ISBM fishery catch.

The outer WCVI sport fishery occurs primarily in the Barkley Sound, outer Clayoquot Sound, and Nootka Sound areas. The majority of fishing effort occurs from mid-July through August in NWVI and August through mid-September in the SWVI. Creel surveys were conducted from early June to mid September. For the outside sport fishery, the Chinook salmon daily bag limit was two Chinook salmon greater than 45 cm . Barbless hooks were mandatory.
The 2010 WCVI AABM sport catch estimate during the creel period was 54,924 Chinook salmon (Table 1.5). Catch rates were determined from anglers interviewed June 1 to September 15. No creel surveys occurred between October and May, when effort is relatively low.

### 1.2 Estimates of Incidental Mortalities in Aggregate Abundance Based Management Fisheries

### 1.2.1 Southeast Alaska Fisheries

Estimates of encounters and IM in SEAK fisheries are shown in Table 1.6 to Table 1.11. Data in Tables 1.6-1.11 were updated back to 2005 to reflect changes in catch estimates (see footnote in Appendix A1). Estimates were converted from landed catch into treaty catch by multiplying the landed catch estimate of encounters by the ratio of treaty catch to landed catch for each respective fishery. The 2010 troll encounters were estimated from regressions of historical encounter estimates and troll effort. The regression predicts encounter estimates from troll effort using encounter estimates obtained from direct fishery observation programs conducted during a series of years. The retention and CNR sublegal regressions use a data series from 1998-2006, while the CNR legal regression uses a data series from 1985-1988 and 1998-2006. Sport fishery releases were computed from the number of Chinook salmon caught and released as recorded on the annual Statewide Harvest Survey (mail-in survey) forms. Legal and sublegal CNR purse seine encounters were calculated using a modified catch per landing approach that uses the relationship between the yearly catch and the magnitudes of legal and sublegal CNR encounters for years where direct observational data are available. For the gillnet fishery, drop-off mortality was estimated as a percentage of the landed catch using the regional-specific drop-off rate for SEAK (CTC 2004c). Encounter estimates are multiplied by the respective IM rate found in CTC (1997) to obtain estimates of IM.

Table 1.6 Estimated treaty encounters in Southeast Alaska troll fisheries for 2002-2010.

| Year | Summer CNR Period |  | CR Period |

### 1.2.2 British Columbia Fisheries

### 1.2.2.1 Northern British Columbia Fisheries

Table 1.12 and Table 1.13 summarize encounters for the NBC AABM fisheries from 2002 to 2010 by size class during retention and Chinook Non-Retention (CNR) fishing periods. Releases for the NBC troll fishery are based on logbook data. Encounters for the QCI sport fishery are based on creel survey and logbook programs. Table 1.14 and Table 1.15 summarize the incidental mortalities associated with the NBC troll and sport encounters. Tables 1.14 and 1.16 presents IM estimates using size specific rates from the CTC (1997). The estimated total in 2010 was 147,669 nominal fish, including 136,613 fish in the landed catch and 11,056 fish from IM (Table 1.14 and Table 1.15).

${ }^{1}$ Legal drop-off mortality is computed from landed catch, incorporating both an encounter ratio and a mortality rate. Refer to List of Acronyms for definitions.

### 1.2.2.2 West Coast Vancouver Island Fishery

The estimated total mortality of Chinook salmon in the WCVI AABM fisheries in 2010 was 155,064 nominal fish, including 139,047 Chinook salmon in the landed catch and 16,017 fish from IM (Table 1.16 and Table 1.17). The estimated IM included 12,185 legal and 3,832 sublegal nominal fish. The estimates for the commercial troll fisheries in 2010 are based on landed catch multiplied by encounter rates from previous years. Table 1.18 and

Table 1.19 summarize encounters for these fisheries by size class during retention and CNR fisheries. In 2010, a non-retention AABM troll fishery opened in September to collect sublegal Chinook salmon DNA samples.

### 1.3 Review of Individual Stock Based Management Fisheries

### 1.3.1 Canadian Individual Stock Based Management Fisheries

The Canadian ISBM fisheries include all fisheries that harvest or release Chinook salmon in British Columbia that are not AABM fisheries. In 2010, 164,145 Chinook salmon were harvested in Canadian ISBM fisheries in British Columbia and Canadian sections of the Transboundary Alsek, Taku and Stikine Rivers. Total estimated IM in 2010 was 9,391 legal and 6,894 sublegal Chinook salmon. The distribution of the landed catches and estimated incidental mortalities are presented in Table 1.20. Historical catches are in Appendixes A2 through A8. Troll and net catches from 1996-2004 have been updated with data from DFO (2009). The former Georgia Strait and Fraser River Appendix has been separated into two Appendix tables and the series of Fraser data has been updated.

### 1.3.2 Southern U.S. Individual Stock Based Management Fisheries

Southern U.S. fisheries of interest to the PSC, generally those north of Cape Falcon, Oregon, are managed in accordance with legal obligations stemming from treaties between Indian tribes and the United States. In 1974, U.S. v Washington set forth sharing obligations to meet treaty fishing rights in western Washington. Treaty rights of Columbia River tribes were defined by U.S. v Oregon, and the Columbia River Fisheries Management Plan was implemented in 1977. In reporting these fisheries, fishermen are termed "treaty" if they are fishing under the Native American Treaty fishing rights and "non treaty" otherwise. As specified in the 2008 agreement, all southern U.S. fisheries are ISBM fisheries. Historical catches in these fisheries may be found in Appendices A. 8 through A. 14 .
1.3.2.1 Strait of Juan de Fuca and the San Juan Islands

The preliminary estimate of the 2010 Chinook salmon catch in Strait of Juan de Fuca tribal net fisheries was 2,245 fish with the majority of these taken during fisheries targeting Fraser River sockeye. There were 5,950 Chinook salmon harvested in the San Juan Islands net fisheries. The preliminary estimate of the 2010 Strait of Juan de Fuca treaty troll fishery is 2,011 Chinook salmon through December. The catch estimate does not include catches from Area 4B during the May-September Pacific Fisheries Management Council management period. Historic catch estimates are provided in Appendices A. 9 and A. 10 for the Strait of Juan de Fuca and San Juan areas respectively.

### 1.3.2.2 Puget Sound

The preliminary estimate of the 2010 tribal and non-tribal net fishery harvests in Puget Sound marine areas is 40,357 ( 32,775 tribal, 7,582 non-tribal) for all marine areas excluding Strait of Juan de Fuca (Area 4B, 5, 6, 6A, 6B, and 6C) and San Juan Islands (Area 7 and 7A). Additional tribal net harvest occurred in freshwater fisheries with a preliminary estimate of 32,219. Estimates of the sport catch in 2010 are not yet available. Historic catch tables for Puget Sound exclusive of the Strait of Juan de Fuca and San Juan Islands are provided in Appendix A.11.

### 1.3.2.3 Washington Coast Terminal

Tribal commercial, ceremonial and subsistence fisheries harvested 2,373 Chinook salmon in north coastal rivers (Quinault, Queets, Hoh, and Quillayute) in 2010. An additional 10 Chinook salmon were harvested by the Makah tribal fisheries in the Waatch and Sooes Rivers.
Harvest in Grays Harbor includes catch from both the Humptulips and Chehalis Rivers. The 2010 tribal net fisheries harvested an estimated 1,526 Chinook salmon. The 2010 non-Indian commercial net harvest in Grays Harbor was 1,239 Chinook salmon. Approximately 8,095 Chinook salmon were harvested by non-Indian commercial net fisheries in Willapa Bay in 2010.
From Grays Harbor north, sport fisheries were implemented based upon pre-season tribal-state agreements and were subject to in-season adjustment. Estimates of sport fishery catches for Washington coastal terminal fishing areas in 2010 are not available. Historic catch estimates for Washington Coastal inside fisheries are shown in Appendix A.12.

### 1.3.2.4 Columbia River

Chinook salmon from the Columbia River are divided into eight stock groups for management purposes. These groups are delineated by run timing and area of origin: (1) spring run originating
below Bonneville Dam; (2) spring run originating above Bonneville Dam; (3) summer run originating above Bonneville Dam; (4) fall run returning to Spring Creek Hatchery; (5) fall run originating in hatchery complexes below Bonneville Dam; (6) wild fall run originating below Bonneville Dam; (7) upriver bright fall run; and (8) mid-Columbia bright fall hatchery fish.
In 2010, the total annual harvest for all fisheries (spring, summer and fall) in the Columbia River basin was 415,441 Chinook salmon, which included non-Indian commercial net harvest of 87,082, sport harvest of 143,472 and treaty Indian commercial, ceremonial and subsistence harvest of 184,887 Chinook salmon. Historic catch estimates for Columbia River fisheries are shown in Appendix A14.

### 1.3.2.5 Oregon Coast Terminal

Most harvest in ocean fisheries off Oregon's coast is comprised of a mixture of southern Chinook salmon stocks not included in the PSC agreement. These stocks do not migrate north into the PSC jurisdiction to any great extent. Some stocks originating from Oregon coastal streams do migrate into PSC fisheries, including the North Oregon Coastal (NOC) and MidOregon Coastal (MOC) stock aggregates. The NOC stocks are harvested only incidentally in Oregon ocean fisheries, while the contribution of MOC stocks to Oregon ocean fisheries is believed to be much greater. Catch statistics are readily available only for a terminal area troll fishery on one MOC stock at the mouth of the Elk River. Late season (October-December) troll catch in the Elk River terminal troll fishery in 2010 was 1,315 Chinook salmon.

Sport catch of these two stock groups occurs primarily in estuary and freshwater areas as mature fish return to spawn and is reported through a "punch card" accounting system. These data are only available more than two years after the current season. Therefore, only the inriver and estuary sport catch though 2009 is reported for the NOC and MOC groups. The 2009 punch card estimate of estuary and freshwater catch for the NOC and MOC groups is 16,647 Chinook salmon. Historical catch estimates for the Elk River troll fishery and the estuary and freshwater sport fisheries targeting on MOC and NOC stocks are shown in Appendix A.15.

### 1.3.2.6 North of Cape Falcon

Ocean fisheries off the coasts of Washington, Oregon, and California are managed under regulations recommended by the Pacific Fishery Management Council. The estimated catch of Chinook salmon in commercial troll fisheries from Cape Falcon, Oregon to the U.S.-Canada border in 2010 was 89,601 for both treaty and non-treaty fisheries combined. Estimated catch in the ocean sport fishery north of Cape Falcon in 2010 was 38,686 Chinook salmon. Historic catch estimates for U.S. ocean fisheries north of Cape Falcon are shown in Appendix A.13.

### 1.4 Estimates of Incidental Mortality for Southern U.S. Fisheries

Table 1.21 shows estimates of incidental mortalities for Washington Coast (WAC) and Puget Sound (PS) fisheries. Sources of estimates are shown in the table footnotes. No estimates of incidental mortalities were provided for 2010 for ocean fisheries south of Cape Falcon or COLR fisheries.

Table 1.21 Estimated incidental mortality in Southern U.S. troll, net, and sport fisheries for 2010.

| Fishery | Troll | Net $^{\mathbf{1}}$ | Sport |

## 2 CHINOOK SALMON ESCAPEMENTS

### 2.1 Introduction

The Agreement established a Chinook salmon management program that:
"introduces harvest regimes that are based on estimates of Chinook salmon abundance, that are responsive to changes in Chinook salmon production, that take into account all fishery induced mortalities and that are designed to meet MSY or other agreed biologically-based escapement objectives"

This chapter compares annual escapement estimates with maximum sustained yield (MSY) or other agreed biologically-based escapement goals established for Chinook salmon stocks. The CTC has reviewed and accepted escapement goals for 25 stocks included in this report.
This annual report, like those prior to 2006 (see CTC 2005a) includes a section on the framework used for escapement assessments and narratives for each stock that includes a description of escapement methodology, escapement goal basis, and agency comments. Annual reports from 2006-2010 used an abbreviated narrative for each stock.

Escapement goals accepted by the CTC were based on analyses that followed the guidelines developed in the CTC escapement goal report (CTC 1999). In the stock-specific narratives presented with the escapement graphs, only CTC-accepted escapement goals and ranges (in gray shading) are shown on the escapement graphs and used for evaluation. Table 2.1 presents the status of escapement goal reviews by the CTC for stocks identified as escapement indicator stocks.

Table 2.1 Pacific Salmon Commission Chinook salmon escapement indicator stocks, where shading indicates that there is not a Chinook Technical Committee accepted escapement goal for assessment of stock status.

### 2.2 Escapement Goal Assessments

The Agreement directs the CTC to "report annually on the escapement of naturally spawning Chinook salmon stocks in relation to the agreed escapement objectives referred to below, evaluate trends in the status of stocks, and report on progress in rebuilding of naturally spawning Chinook salmon stocks" (Annex IV, Chapter 3, Paragraph 1.b.iii). In this report, escapement assessments include stock specific graphs of escapements and commentary, presented to provide a perspective on stock status and escapement trends through 2010.

The escapement goals and 2010 escapements for the 25 stocks with CTC accepted escapement goals are listed in Table 2.2. For 12 of these stocks, the agency escapement goal is defined as a range; for the remaining 13 stocks, the escapement goal is defined as a point estimate. In 2010, escapements were within the goal range for six stocks, above the range or Smsy point estimate for 14 stocks, and below the goal for five stocks.

The CTC has now assessed the status of stocks with CTC-accepted goals for return years 1999-2010. Over this time period, the number of stocks with CTC-accepted goals has increased from 16 to 25 (Figure 2.1). From 1999-2009, the percentage of stocks that met or exceeded escapement goals or goal ranges has varied from $46 \%$ to $96 \%$. In 2010, the percentage of stocks that met or exceeded goal was $80 \%$, the highest percentage observed since 2005. Of the five stocks below goal, one stock (Hoh Spring/summer) was within $15 \%$ of the target goal. Four stocks were more than $15 \%$ below goal: Situk, Cowichan, Queets spring/Summer, and Nehalem.

Table $2.2 \quad$ Escapement goals, 2009 and 2010 escapements, and 2011 forecasts for stocks with Chinook Technical Committee agreed goals. Percentages relative to goals are in parentheses. Escapements below the goal or lower bound of the escapement range are shaded; escapements or forecasts below the $85 \%$ threshold applicable to Attachment I-III are bold.

| Stock | Region | Stock Group | Escapement Goal | $2009$ <br> Escapement | $2010$ <br> Escapement | $2011$ <br> Forecast |

${ }^{1}$ May not be directly comparable to the escapement goal since accounting methods differ from those used to develop the goal.
Refer to List of Acronyms for definitions.

Figure 2.1 Number and status of stocks with Chinook Technical Committee accepted escapement goals for years 1999-2010.

### 2.3 Paragraph 13 Escapement Analysis

Paragraph 13 of the 2008 Agreement describes a process to implement additional management actions in AABM and ISBM fisheries if the management as prescribed in paragraphs 8 and 10 fail to meet MSY or other biologically-based escapement objectives. Paragraph 13 details a process for evaluating stock groups and indicator stocks listed in Attachments I-II to determine if additional management actions should be implemented in AABM fisheries. If additional management action is required, relevant ISBM fisheries for stocks also listed in Attachments IV and V would commensurately be reduced to increase the escapements of the depressed Chinook salmon stocks within the stock groups triggering the additional management actions. The CTC is to notify the Commission of any proposed fishery restrictions to be implemented under Paragraph 13 at the February Annual Meeting.

Additional management actions for SEAK or NBC AABM fisheries would reduce Table 1 catch limits by $10 \%$ if a majority of stocks with agreed management objectives in at least two of the stock groups listed in Attachment I and II of the Chinook salmon Annex were observed:

- at least $15 \%$ below their escapement goal management objectives for the past year and are forecast to be at least $15 \%$ below their escapement goal objectives in the upcoming year; or
- at least $15 \%$ below their escapement goal objectives for the past two consecutive years (unless a forecast for escapement will exceed the escapement objective in the coming year).

If three or more stock groups in Attachments I and II meet the criteria to trigger additional management action, Table 1 catch limits in the relevant AABM fishery would be reduced by 20\%. For the WCVI AABM fishery, Attachment III of the 2008 Agreement lists stock groups applicable to the obligations defined in paragraph 13. However, in consideration of the 30\% reduction in catch limits for the WCVI AABM fishery, the 2008 Agreement states that additional actions will not be taken for this fishery except as otherwise may be agreed by the Commission.

The 2008 Agreement directs the CTC to provide a review of Attachments I-V by 2014 or earlier, to determine if the current lists of stock groups continue to be appropriate, if there are new criteria that could be employed to revise stock group listings for each attachment, and whether any changes to the Attachments proposed by a Party may be appropriate. In the interim, the CTC in this report provides an evaluation of the stocks listed in Attachments I-III in relation to the criteria described in Paragraph 13.

In Table 2.3, the CTC summarizes the performance of the stock groups and the criteria for initiating additional management action in regards to Paragraph 13, based upon observed escapements and exploitation rates through 2010 and stock forecasts for 2011. For SEAK and NBC AABM fisheries, the stock groups in Attachment I and II are identical, and thus are combined in Table 2.3. All stocks relevant to Paragraph 13 decisions for SEAK and NBC AABM fisheries have escapement based management objectives. Although not meeting management objectives does not automatically trigger reductions in the WCVI AABM fishery, the CTC included an evaluation of the stock groups in Attachment III to inform the Commission of the performance of the stock groups in Attachment III in relation to the provisions of Paragraph 13. For the WCVI AABM fishery, stocks in the Puget Sound Summer/Fall stock group include three stocks with exploitation rate management objectives which have yet to be submitted for CTC review.

Table $2.3 \quad$ Evaluation of criteria for initiating additional management action in regards to Paragraph 13 of the Chinook salmon Chapter of the Pacific Salmon Treaty 2008 Agreement. When the stock group cannot be evaluated because an insufficient number of stocks in the group have agreed escapement objectives, or that forecasts were not provided to the Chinook Technical Committee for stocks with agreed escapement objectives, NA is shown.

|  |  |  | Stocks <br> with <br> agreed <br> Fishery | Number <br> below <br> threshold <br> (2009 and <br> 2010) | Stocks <br> with a <br> 2011 <br> forecast | Number of <br> 2011 <br> forecasts <br> below <br> threshold | Paragraph <br> 13 criteria <br> met |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| SEAK/ <br> NBC | North/Central British <br> Columbia | 3 | 0 | NA | 0 | NA | No |
|  | Upper Strait of Georgia | 5 | 0 | NA | 0 | NA | No |
|  | West Coast Vancouver <br> Island Falls | 7 | 0 | NA | 0 | NA | No |
|  | Far North Migrating <br> Oregon Coastal Falls | 3 | 3 | 1 | 3 | 0 | No |
|  | Columbia River Falls | 3 | 3 | 0 | 2 | 0 | No |
|  | Columbia River Summers | 1 | 1 | 0 | 1 | 0 | No |
|  | Washington Coastal Fall <br> Naturals | 5 | 3 | 0 | 0 | NA | No |
|  |  <br> Summers) | 3 | 0 | NA | 0 | NA | No |
| WCVI | Columbia River Falls | 3 | 3 | 0 | 0 | 0 | No |
|  | Fraser Late | 1 | 1 | 0 | 0 | NA | No |
|  | Puget Sound Natural <br> Summer/Falls | 5 | 0 | NA | 0 | NA | No |
|  | Columbia River Summers | 1 | 1 | 0 | 0 | 0 | No |

No stock groups listed in Attachment I-III met the criteria for triggering additional management action under Paragraph 13 for either the 2009 and 2010 observed values or the 2010 observed and 2011 forecast values (Table 2.3). However, the CTC could not evaluate if any of the stocks met the conditions in Paragraph 13(d), because harvest levels for ISBM fisheries were not yet available for 2010. Only one stock with an agreed escapement objective, the Nehalem in the NOC stock group, was more than 15\% below the management objective in both 2009 and 2010. All stocks in the NOC stock group, including the Nehalem, are forecasted to be above the escapement goal in 2011 (Table 2.2).

Only five of the 10 different stock groups in Table 2.3 have stocks with agreed management objectives that can be evaluated for triggering additional management action. These five stock groups contain 13 stocks, of which 11 have agreed escapement objectives. Of the 11 stocks, forecasts for 2011 were available for six (Table 2.3). The CTC has identified a need to develop management objectives and forecast capabilities for more of the stocks included in Attachments I-III to improve the efficacy of the Paragraph 13.

This analysis was done well after the February timing required by the 2008 Agreement for the CTC to notify the Commission of any proposed fishery restrictions to be implemented under Paragraph 13 for the 2011 fishing season due to data availability. Much of the escapement data for 2010 and forecasts for 2011 were not provided until after June. Also, the CTC has not yet set the standards for precision and accuracy for forecasts and predictions used to develop Table 2.3. These data standards will be required before the evaluations that rely on forecasts can be used to recommend additional management action. However, the CTC has carried out the evaluation of the Paragraph 13 criteria, with the exception 13(d) and (e), to provide insight into current status of stocks in relation to the criteria and to identify data needs for the application of Paragraph 13. To meet the timing requirement for implementation of Paragraph 13, the CTC would need before the February Annual Meeting: a) escapement and exploitation rate estimates for the prior year for stocks included in Paragraph 13 Attachments I-V; and b) projections of exploitation rates and forecasts of escapements for the coming year for these same stocks.

As noted above, the Commission has assigned the CTC to review Attachments I-V and to provide recommendations on their use to the Commission. In its review, the CTC will consider the schedule of needed information for evaluation of the stock group criteria to determine how early in the annual cycle recommendations for additional management actions under Paragraph 13 can be provided to the Commission.

### 2.4 Trends and Profiles for Escapement Indicator Stocks

Graphs of time series of escapements and terminal runs for Chinook salmon stocks are included in sections for Alaska, Canada, and Washington/Columbia River/Oregon. Each graph contains the name of the stock and the type of data depicted (total escapement, index counts, terminal runs, etc.). A limited commentary is also provided for each stock. For the graphs that include estimates of the terminal run size, the harvests in terminal runs, in some cases, include both jacks and adults, whereas the escapement is usually reported in adults. The $x$-axis represents calendar years. All escapement goals accepted by the CTC are shown except for the LGS stock group because this group includes both the Cowichan and Nanaimo stocks and only the Cowichan has a CTC accepted goal. Historical escapement and terminal run data are provided for SEAK stocks in Appendix B.1, for Canadian stocks in Appendix B.2, for Puget Sound in Appendix B.3, Washington Coastal stocks in Appendix B.4, for Columbia River stocks in Appendix B. 5 and Oregon Coastal stocks in Appendix B.6.

### 2.4.1 Southeast Alaska and Transboundary River Stocks

Of the 11 SEAK and TBR stocks included in the escapement assessment, the Situk, Chilkat, Taku, King Salmon, Stikine, and Unuk Rivers as well as Andrew Creek include estimates of total escapement of large fish, Chinook salmon $\geq 660 \mathrm{~mm}$ mid-eye to tail fork (MEF) length. In most systems these include 3 -, 4 -, and 5-ocean age fish and include almost all females and large males in the stocks; 1- and 2- ocean age males are not included in these estimates except those fish > 659 mm MEF. Escapement estimates for the Chickamin, Blossom, and Keta Rivers are index counts of large fish. These indices are enumerated from aerial helicopter surveys that represent a fraction (one-third to one-fifth) of the total number of large spawners. Except for the Chilkat River, survey methods have been standardized for all systems since 1975. The assessment of Chilkat River Chinook salmon was standardized in 1991 as an annual mark-recapture (MR) estimate of escapement. Escapement goals have been defined as a range for the SEAK/TBR stocks, shown by the grey shaded area on the graphs. Escapement estimates for the Alsek River are estimates of total escapement of age-1.2 fish and older.

The SEAK and TBR stocks can be classified into two broad categories, inside-rearing and outside-rearing, based on ocean migrations. Outside-rearing stocks have limited marine rearing in SEAK and are caught primarily during their return spawning migrations in the spring; these stocks include Chinook salmon returning to the Situk, Alsek, Taku, and Stikine Rivers. Insiderearing stocks are vulnerable to SEAK and NBC fisheries as immature fish as well as during their spawning migrations and include the other seven SEAK and TBR indicator stocks. Note that there is some overlap in these stocks within these two broad classifications. All SEAK and TBR indicator stocks produce primarily yearling smolt except the Situk River, which presently produces primarily sub-yearling smolt. Sub-yearling smolts comprise about $10 \%$ of the annual runs in the Keta and Blossom Rivers.

The Alaska Department of Fish and game (ADF\&G) established a 15-year rebuilding program in 1981 (ADF\&G 1981). ADF\&G established interim point escapement goals in 1981 for all 11 systems, based on the highest observed escapement count prior to 1981. ADF\&G (and CDFO for three TBR stocks) have subsequently revised escapement goals that have been reviewed and accepted by the CTC for all eleven stocks, some more than once. ADF\&G uses escapement goal ranges in conformance with the ADF\&G Salmon Escapement Goal Policy and Sustainable Salmon Fisheries Policy. These ranges are shaded in grey in graphs of escapements for the SEAK/TBR stocks.

Escapement Methodology: The Situk River is a non-glacial system located near Yakutat, Alaska, that supports a moderate-sized, outside-rearing stock of Chinook salmon. Escapements are based on weir counts minus upstream sport fishery harvests (if any), which are estimated from an on-site creel survey and a post season mail-out survey. The weir has been operated annually since 1976, and was also operated from 1928-1955. Counts of large Chinook salmon are reported as the spawning stock. Jacks (1- and 2-ocean-age fish) are also counted and, since 1989, jack counts (not included in the graph above) have ranged between 1,200 and 4,000 fish.

Escapement Goal Basis: In 1991, ADF\&G revised the Situk River Chinook salmon escapement goal to 600 large spawners based upon a spawner-recruit analysis (McPherson 1991), which was reviewed and adopted by the CTC. In 1997, ADF\&G revised the Situk River escapement goal range to 500-1,000 large spawners to conform to the department's escapement goal policy. The CTC reviewed and accepted this change in 1998. ADF\&G changed the goal range to 450-1,050 large spawners in 2003; this range was reviewed by the CTC in 2004 but not accepted.

Agency Comments: During the 35 -year period of 1976-2010, the Situk escapements have been below the goal range three times, in 1982, 2008 and 2010. Directed sport, commercial and subsistence fisheries located both inside the river and inlet and in nearby surf waters target this stock under a management plan to achieve escapements within the range. Total annual terminal catcht rates from all gear groups have averaged about 60\% from 1990-2003. Catcht rates have been lower since 2004, as this stock has experienced poor survival for recent brood years. In 2010, the escapement was 167 large Chinook salmon, $33 \%$ of the lower end of the escapement goal range; however, the weir was out for a 3-day period and an undetermined number of spawners were not counted. Sport and commercial fisheries were restricted to non-retention of Chinook salmon in 2010.

Escapement Methodology: The Alsek River is large transboundary glacial system that originates in the SW Yukon Territory and NW British Columbia and flows into the Gulf of Alaska about 50 miles east of Yakutat. This river supports a moderate run of outside-rearing Chinook salmon. Since 1976 escapements have been principally monitored by a weir operated at the Klukshu River, one of 51 tributaries of the Tatshenshini River, the principal salmonproducing branch of the Alsek River. In previous reports, index escapements using a weir operated at the Klukshu River were presented for this stock. These have been replaced with estimates of total escapement, drainage-wide, including direct MR estimates for 1998-2004. All other years are Klukshu River weir counts expanded by the average expansion (4.00) factor from 1998-2004.

Escapement Goal Basis: During this cycle, a revised goal of 3,500 to 5,300 total spawners (fish age-1.2 and older) was accepted by the CTC, ADF\&G, and Canadian Science Advisory Pacific, based on analysis in Bernard and Jones (2010). Prior to this, the goal was based on the escapement of fish through the Klukshu River weir (McPherson et al. 1998).

Agency Comments: Directed Canadian sport and aboriginal fisheries occur in various upriver sections of the Alsek River. Some Chinook salmon are caught as bycatch in the U.S. sockeye directed fishery that takes place inriver near the estuary and within the estuary. A few Chinook salmon are also caught in a U.S. subsistence fishery that takes place in the same area as the U.S. sockeye fishery. Total annual harvest rates have averaged 12\% since 1976 (Bernard and Jones 2010). Escapements in the Alsek River have averaged 9,500 Chinook salmon over the 35 -year period of 1976-2010. The 2010 escapement was 9,428 Chinook salmon based on the Klukshu weir count of 2,357 expanded by a factor of 4.0 . The joint ADF\&G-CDFO assessment is that the Alsek River stock is healthy but underutilized.

Escapement Methodology: The Taku River is a large, glacial, transboundary river that originates in northern British Columbia and flows into Taku Inlet east of Juneau, Alaska. This river supports a large, outside-rearing run of Chinook salmon. In 1989, 1990, and 1995-2010 escapements were estimated using MR methods. In other years since 1975, aerial counts were expanded by a factor of 5.2 , the 5 -year average of the ratio of the mark-recapture estimates to aerial survey counts (McPherson et al. 2010).

Escapement Goal Basis: During this cycle, a revised goal of 19,000 to 36,000 large Chinook salmon (age-. 3 to -.5 fish) was accepted by the CTC, ADF\&G, TBR Panel, and Canadian Science Advisory Pacific, based on the analysis in McPherson et al. (2010). Prior to this, the goal was based on the escapement of fish that optimized smolt production (McPherson et al. 2000).

Agency Comments: Estimated harvest rates on this stock averaged 9.8\% since 1973 (McPherson et al. 2010). In recent years of directed Chinook salmon fishing, total harvest rates on Taku River Chinook salmon were higher, $45 \%$ and $34 \%$ in 2005 and 2006.respectively. Most harvests occur in the U.S. commercial gillnet and sport marine fisheries in District 111 near Juneau and inriver in the Canadian gillnet and aboriginal fisheries that occur mostly just above the U.S./Canada border. Juvenile Chinook salmon were marked with CWTs from 1976 through 1981 and annually since 1993 (1991 brood). Data from recoveries of these CWTs from fisheries and inriver assessment projects provides the information needed for estimation of adult and smolt production. Since 1985, estimated escapements have been within or above the escapement goal range except in 1999 and 2007. In 2010, an estimated 29,307 large fish escaped into the Taku River and the joint ADF\&G-CDFO assessment is that the stock is healthy.

Escapement Methodology: The Stikine River originates in British Columbia and flows into central Southeast Alaska near the towns of Petersburg and Wrangell. This is the largest river emptying into SEAK, glacial in origin, and supports a large, outside-rearing stock of Chinook salmon. From 1975 through 1984, index escapements were made using survey counts and since 1985, counts were made using a weir at the Little Tahltan River. Since 1996, MR experiments were conducted annually to estimate total escapement. These studies indicate the weir counts represented $17 \%$ to $20 \%$ of the total escapement (Pahlke and Etherton 1999).

Escapement Goal Basis: An escapement goal of 14,000 to 28,000 large Chinook salmon (age. 3 to -.5 fish) was established in 1999 after review and acceptance by the CTC, ADF\&G, TBR Panel, and Canadian Science Advisory Pacific, based on the analysis in Bernard et al. 2000. Prior to this, several system-wide or index goals were developed by the U.S. and Canada and were based on limited data.

Agency Comments: In recent years of directed Chinook salmon fishing, total catch rates on Stikine River Chinook salmon are believed to have ranged between $50 \%$ and $70 \%$. Most catches occur in the U.S. commercial gillnet and sport fisheries in District 108, near Petersburg and Wrangell, and inriver in the Canadian gillnet and aboriginal fisheries. CDFO and ADF\&G currently operate joint programs to CWT smolt in order to estimate smolt and adult production, as well as exploitation. Since 1985, escapements to the Stikine River were within or above the escapement goal range except in 2009. In 2010, an estimated 15,177 large fish escaped into the Stikine River and the joint ADF\&G-CDFO assessment is that the stock is healthy.

Escapement Methodology: The Chilkat River is a moderate-sized glacial system located near Haines, Alaska which supports a moderate-sized, inside-rearing stock of Chinook salmon. Escapements are based on estimates of large spawners from a MR program annually since 1991 (Ericksen and McPherson 2003). The escapement database for this stock since 1991 is relatively precise, with coefficients of variation for annual escapements averaging 15\%. From 1975-1992, aerial survey counts were conducted on two small tributaries with relatively clear water; results from these estimates were inconsistent. Radio telemetry studies conducted in 1991 and 1992 found that spawners in these two tributaries represented less than $5 \%$ of the total escapement, and did not represent trends in abundance, so aerial surveys were discontinued.

Escapement Goal Basis: The 1981 escapement goal was set at 2,000 large fish, based on an assumed fraction of the total escapement represented by discontinued survey counts. In 2003, a revised escapement goal range of 1,750 to 3,500 large Chinook salmon spawners was recommended, based on the MR estimates of escapement and limited CWT information available for this stock (Ericksen and McPherson 2003) . This goal range was reviewed and adopted by ADF\&G and the Alaska Board of Fish in 2003 and subsequently reviewed and accepted by the CTC.

Agency Comments: Smolt from this stock have been CWTd at relatively high rates (8-10\%) beginning with the 1999 brood year; additional wild-stock tagging occurred for 3 broods prior to that time. Relatively small terminal U.S. marine sport and subsistence fisheries target this stock. This stock is also caught incidentally in SEAK sport, commercial drift gillnet and troll fisheries in northern SEAK. Available CWT information on this stock suggests that exploitation is about 20\% for recent brood years from the CTC ERA. Escapements since 1991 have been within or above the escapement goal range in all years except 2007. The preliminary escapement in 2010 was estimated at 1,852 large spawners, near the lower end of the escapement goal range.

Escapement Methodology: The King Salmon River is a small non-glacial system located on Admiralty Island southeast of Juneau that supports a small, inside-rearing stock. Escapements of large Chinook salmon are based upon weir counts from 1983-1992 and expansions of survey counts from 1971 to 1982 and 1993 to 2010. A weir was operated for 10 years (1983-1992) along with the surveys and, on average the total escapement was 1.52 times the survey count (McPherson and Clark 2001). Jacks (2-ocean-age fish) represented an average of $22 \%$ of the weir counts from 1983-1992 and are not included in the graph above.

Escapement Goal Basis: In 1981, ADF\&G set the index goal at 200 large fish based upon peak survey counts of 200 spawners in 1957 and 211 spawners in 1973. In 1997, ADF\&G revised the goal to 120-240 total large fish based upon a spawner-recruit analysis for the 1971-1991 brood years (McPherson and Clark 2001). The analysis and goal range was accepted by the CTC in 2001.

Agency Comments: There is no terminal fishery targeting this stock, though harvests of immature and mature fish occur in SEAK fisheries. Since 1981, escapements have been within or above the accepted range except in 1992 and 2009. The estimated escapement in 2010 was 158 large spawners. Survey conditions in 2010 were noted as normal.

Escapement Methodology: Andrew Creek, near Petersburg, Alaska, is a small non-glacial U. S. tributary of the lower Stikine River that supports a moderate run of inside-rearing Chinook salmon. Escapements are based upon weir counts from 1976 to 1984 and expansions of index counts in 1975 and 1985 to 2010. Four years of concurrent weir and index count data were used to estimate the expansion factor of 1.95 . Jacks have represented an average of $19 \%$ of the weir counts and are not included in the above graph.

Escapement Goal Basis: In the early 1980s, ADF\&G set the Andrew Creek Chinook salmon escapement goal at 750 large fish (total escapement). In 1997, an initial stock-recruit analysis was developed that underwent review by ADF\&G and the CTC. This analysis was completed in 1998 and the technical report (Clark et al. 1998) recommended a revised biological escapement goal range of 650 to 1,500 large Chinook salmon that was accepted and adopted by the ADF\&G and the CTC.

Agency Comments: Before 1976 a large terminal marine gillnet fishery occurred in the spring, targeting Stikine River and other nearby Chinook salmon stocks. Harvests of immature and mature fish Andrew Creek occur primarily in SEAK and to a small extent in NBC fisheries, based on CWT recoveries of Chinook salmon from SEAK hatcheries using Andrew Creek brood stock. Escapements since 1986 have all been above the lower end of the biological escapement goal range of 650 to 1,500 , except in 1997 and 2009 when they were $<5 \%$ below the range. The estimated escapement in 2010 was 1,205 large spawners, within the upper half of the range.

Escapement Methodology: The Unuk River is a moderate-sized glacial system that supports a moderate run of inside-rearing Chinook salmon. Escapements are estimates of total escapement of large spawners. The estimates are based on MR estimates from 1997 to 2010 and expanded survey counts from 1977 to 1996. Radio telemetry studies in 1994 and 2007 showed that the surveys are conducted in stream reaches where $80 \%$ of the spawning occurs; the expansion factor for survey counts is 4.83 (Hendrich et al. 2008).

Escapement Goal Basis: In 1994, ADF\&G revised the Unuk escapement goal to 875 large spawners in survey (index) counts, based upon the spawner-recruit analysis reported by McPherson and Carlile (1997), which the CTC reviewed and accepted in 1994. In 1997, ADF\&G revised the goal to a range of 650-1,400 large index spawners as recommended in the McPherson and Carlile (1997) report and in compliance with the ADF\&G Escapement Goal Policy. The CTC reviewed and accepted this change in 1998. Since the expansion factor for surveys was unknown at that time, the goal was expressed in survey count currency. In 2008, a more extensive analysis was done with spawners, recruitment and fishing mortality expressed in total numbers of fish because of the extensive number of MR estimates of escapement and CWT data available (Hendrich et al. 2008). The analysis included the 1982-2001 brood years. The CTC accepted a range of 1,800 to 3,800 large spawners, with a point estimate of 2,764 , in 2009.

Agency Comments: Catches of immature and mature fish occur in SEAK and NBC fisheries. On average, for the 1992-2001 broods, catch by gear sector was 47\% SEAK troll, 36\% SEAK sport, $10 \%$ SEAK net and most of the remainder caught in NBC. About 55\% of the catch is taken in the southern inside area of SEAK (mostly troll and sport). Estimated annual catch rates averaged about 27\% in nominal numbers and 24\% in AEQs from 1985 to 1998 (Hendrich et al. 2008). Coded-wire tagging of this stock was conducted for the 1982-1986 (Pahlke 1995) and the 1992-present broods; this stock is now an exploitation rate indicator stock. In the 34 years since 1977, the estimated escapements have been within or above the escapement goal range each year. The estimated escapement in 2010 escapement was 4,290 large spawners, slightly above the escapement goal range.

Escapement Methodology: The Chickamin River is a moderate-sized glacial system that supports a moderate run of inside-rearing Chinook salmon, based on wild-stock CWTs. Reported escapements shown above are survey counts (unexpanded highest single-day counts) of large fish in eight tributaries using standardized methodology (Pahlke 2003). MR studies in 1995, 1996 and 2001-2005 found that about $21 \%$ of the total escapement is counted during peak surveys on average (Weller et al. 2007). A radio telemetry study in 1996 indicated that the annual surveys are conducted in stream reaches where over $80 \%$ of all spawning occurs. The expansion factor is estimated at 4.75 for survey counts using the results from the 1996 and 20012005 studies.

Escapement Goal Basis: In 1994, ADF\&G revised the goal to 525 large index spawners based upon a spawner-recruit analysis (McPherson and Carlile 1997), which the CTC reviewed and accepted. In 1997, ADF\&G revised the goal to 450-900 large index spawners as recommended in the McPherson and Carlile (1997) report and in compliance with the ADF\&G Escapement Goal Policy (ADF\&G 1997). The CTC reviewed and accepted this change in 1998.

Agency Comments: There is no terminal fishery targeting this stock; immature and mature fish are caught in marine SEAK and NBC fisheries, with the majority taken in the southern inside quadrant of SEAK by troll and sport gear sectors. There are no subsistence or freshwater fisheries on any Behm Canal Chinook salmon stocks. Coded-wire tagging was conducted for the 1982-1986 broods (Pahlke 1995) and resumed for the 2000-2006 broods. Estimated total exploitation rates for recent broods are about $28-30 \%$ in AEQs under the current management regime. Like the nearby Blossom and Keta Rivers, this stock produces the largest fish at age in SEAK. The time series of survey counts follows 2 cycles: counts for 1975-1981 and 1992-1998 were below the goal range, and those from 1982-1991 and 1999-2010 were all within or slightly above the range. Survey counts since 1999 have averaged 953 large spawners. In 2010, the survey count was 1,023 , which is about $10 \%$ above the range and represents an estimated total escapement of 4,894 large spawners.

Escapement Methodology: The Blossom River is a small-sized non-glacial system that supports a small run of inside-rearing Chinook salmon and empties into Behm Canal near Ketchikan. Indices of escapement since 1975 are peak single-day survey counts of large spawners, standardized since 1975 in area and time (Pahlke 2003). Studies using MR were performed in 1998 and in 2004-2006, in addition to the survey counts. The agency agreed expansion factor is 3.87 for years without MR estimates.

Escapement Goal Basis: In 1994, ADF\&G revised the Blossom River goal to 300 large index spawners based upon a spawner-recruit analysis (McPherson and Carlile 1997), which the CTC reviewed and accepted. In 1997, ADF\&G revised the goal to a range of 250-500 large index spawners in conformance with the McPherson and Carlile (1997) report and in compliance with the ADF\&G Escapement Goal Policy. The CTC reviewed and accepted this change in 1998. In 2010, the ADF\&G submitted a report to the CTC with a revised goal of 150-300 large index spawners. The CTC accepted the revision in June 2011.

Agency Comments: There is no terminal fishery targeting this stock; immature and mature fish are caught in SEAK and NBC fisheries, based on wild-stock and hatchery-stock data from the nearby Unuk and Chickamin Rivers. All waters of east Behm Canal are closed to Chinook salmon fishing year-round. Age data collected since 1998 indicate that about $10 \%$ of the annual run is comprised of progeny from under-yearling smolt. Between 1976 and 1980, survey counts were below the current escapement goal, averaging 93 large fish. These smaller escapements subsequently seeded large runs with resultant large escapements during the six-year period of 1982-1987, with counts averaging 796 fish. This six-year period of larger escapements has been followed by a 23 -year period (1988-2010) of reduced, but relatively stable, spawning abundance averaging 234 large fish in survey counts. The 2010 survey count of 180 large spawners was within the escapement goal range. Survey counting conditions were noted as normal for this system in 2010.

Escapement Methodology: The Keta River is a small-sized non-glacial system southeast of Ketchikan that supports a small run of inside-rearing Chinook salmon. Indices of escapement since 1975 are peak single day survey counts of large spawners, standardized since 1975 in area and time (Pahlke 2003). Total escapement was estimated with MR methodology in 1998, 1999, and 2000 (Freeman et al. 2001). The estimated expansion factor for survey counts is 3.01.

Escapement Goal Basis: In 1994, ADF\&G revised the escapement goal to 300 large index spawners based upon a spawner-recruit analysis (McPherson and Carlile 1997), which the CTC reviewed and accepted in 1994. In 1997, ADF\&G revised the escapement goal to a range of 250500 large index spawners in conformance with the McPherson and Carlile (1997) report and in compliance with the ADF\&G Escapement Goal Policy (ADF\&G 1997). The CTC reviewed and accepted this change in 1998. In 2010, ADF\&G submitted a report to the CTC with a revised goal of 175-400 large index spawners. The CTC accepted the revision in June 2011.

Agency Comments: There is no terminal fishery targeting this stock; immature and mature fish are caughtin SEAK and NBC fisheries, based on wild-stock and hatchery-stock data from the nearby Unuk and Chickamin River. All waters of east Behm Canal are closed to Chinook salmon fishing year round. Age data collected since 1998 indicate that about $10 \%$ of the annual run is comprised of progeny from under-yearling smolt. Like the nearby Blossom River, survey counts were low in the 1970s, rose in the mid to late 1980s and have been relatively stable since that time. Between 1975 and 1981, annual survey counts were within or below the goal of 250-500, averaging 265 large spawners. Production from the 1975-1981 escapements was high and survey counts from 1982 to 1990 averaged 734 large fish. This was followed by a 20-year period (19912010) of relatively stable survey counts, averaging 332 large spawners. The survey count in 2010 was 475 large spawners, under normal counting conditions, which is above the upper end of the escapement goal range.

### 2.4.2 Canadian Stocks

Since the beginning of the Chinook salmon rebuilding program of the 1985 PST, escapement goals for Canadian Chinook salmon stocks were generally based on doubling the average escapements recorded from 1979-1982. The doubling was based on the premise that Canadian Chinook salmon stocks were over-fished and that doubling the escapement would still be less than the optimal escapement estimated for the aggregate of all Canadian Chinook salmon populations (see stock-recruitment curve in "Technical Basis of PSC Catch Ceilings," Figure 1, Attachment 4, PSC file 72006; PSC Office, Vancouver, BC). Doubling was also expected to be a large enough change in escapements to allow detection of the change in numbers of spawners and the subsequent production. The escapement goals of the Canadian stocks are currently being reviewed.

### 2.4.2.1 Northern British Columbia

Escapement Methodology: The Yakoun River is the only significant Chinook salmonproducing stream on Haida Gwaii (the Queen Charlotte Islands). Chinook salmon spawn primarily at the outlet of Yakoun Lake and are a summer-run stock. Visual estimates of escapement were made by foot surveys of the system. These estimates were then expanded into a total estimate of spawning escapement in the system. The effort spent on escapement surveys declined since 2005 and the survey's accuracy (i.e. ability to estimate the actual escapement) was unknown. Escapement estimates are thought to have exceeded 5,000 Chinook salmon since 2005. However the time series has not been continued.

Escapement Goal Basis: There is no CTC accepted escapement goal for this stock.
Agency Comments: A small enhancement program exists on the Yakoun River.

Escapement Methodology: The Nass River is the largest river in Area 3, representing a group of approximately 25 streams in Area 3. Prior to 1992, CDFO observations of escapement were based on visual counts. Programs using MR have been conducted since 1992 by the Nisga'a Fisheries to estimate total spawning escapement in the Nass River. The Nass MR program uses two fish wheels at Gitwinksihlkw (GW) in the lower Nass canyon to apply tags and two wheels at Grease Harbor in the upper canyon and the Meziadin River fishway for recovery. A modified Petersen model was used to estimate the total population of Chinook salmon past the tagging location. Tags were also recovered in upriver fisheries and on the spawning grounds. Spawning escapements were calculated as the estimated Chinook salmon population past GW from the MR studies, less upriver catches in sport and FN fisheries. Three tributaries with Chinook salmon populations enter the Nass River below GW. Visual estimates augmented by fence counts of the Kincolith River in 2001, 2002, 2005 and 2007 were used to estimate Nass River Chinook salmon escapements below the fish wheels.

Escapement Goal Basis: There is no CTC accepted escapement goal for this stock. The Fisheries Operational Guidelines states two goals for managing fisheries: an operational target escapement of 20,000 Chinook on the spawning grounds, and a minimum escapement of 10,000 Chinook. If escapements are projected to be below 10,000 Chinook, then no fishing on Nass River Chinook would be recommended. No biological-basis for an escapement goal has been developed for this system.

Agency Comments: The Nisga’a Fisheries Working group, including CDFO, has accepted the historical escapement and terminal run values. These figures have been revised and are presented in Appendix B2. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for stocks within the Nass River stock group (Parken at al.2006), but estimates of total escapement are needed to make them effective. The SSP at the Nass River (Section 3.1.5.3) and Northern Endowment Funded projects at the Kwinamass and Kateen Rivers will help evaluate spawner levels relative to estimates of $\mathrm{S}_{\text {MSY }}$ and other reference points.

Escapement Methodology: The Skeena Chinook salmon escapements shown above represent 40 streams within the Skeena watershed which are consistently surveyed. The Skeena River supports over 75 separate Chinook salmon spawning populations, but three (Kitsumkalum, Morice, and Bear Rivers) account for about $70 \%$ of the total abundance. A second group of populations (Ecstall, Kispiox, and Babine Rivers) have annual returns ranging from 1,000 to 5,000 spawners, and comprise about $13 \%$ of Skeena returns. Escapement estimates are generally based on visual observations from helicopter, fixed wing aircraft and/or from stream walking surveys. Fish counting weirs are present on the Babine, Sustut and Kitwanga Rivers. The Kitsumkalum River is the exploitation rate indicator stock for the Skeena Chinook salmon complex. Spawning escapements in the Kitsumkalum have been estimated using a MR program since 1984.

Escapement Goal Basis: There is no CTC accepted escapement goal for this stock. Biologically-based goals for this complex of Chinook salmon spawning populations have not yet been developed. Future assessments will partition this large aggregate into stocks by run timing, life history and geographic areas.

Agency Comments: Terminal fishery in the Skeena River would normally include commercial gillnet in the terminal exclusion area (River Gap Slough, Area 4), in-river sport, and aboriginal fisheries. Estimates of in-river sport catch were not available from 1997 to 2002. A creel survey was conducted on the Lower Skeena in 2003 and 2010. Consequently, the 2003 and 2010 total terminal run estimates include lower river sport catch but no estimate of upper river sport catch. Habitat-based estimates of $\mathrm{S}_{\mathrm{MSY}}$ and other stock-recruitment reference points are available for stocks within the Skeena River, but estimates of total escapement are needed to make them effective. There are two SSPs on the Skeena River (see Sections 3.1.5.1 and 3.1.5.2) that will provide estimates of total escapement for the Skeena River and its component tributaries.

### 2.4.2.2 Central British Columbia

Escapement Methodology: The Area 8 Chinook salmon stock consists of seven non-enhanced systems, but the Dean River is the main spawning population. Of all Chinook salmon-producing streams in Areas 5 to 10, the Dean is the best indicator in terms of consistent survey coverage and methodology. Chinook salmon returning to the Dean River have early-summer timing and most spawn in the lower river by July. Up until 2000, counts of spawning Chinook salmon were made during 1-3 surveys and the peak count used as the escapement index. Survey counts were sometimes expanded to account for sections of the river that could not be surveyed in any year, but the counts were not extrapolated to total escapement of Chinook salmon to the river. Since 2001, the annual number of aerial surveys has increased, allowing the calculation of Area-Under-the-Curve (AUC) escapement estimates. In some years viewing conditions were poor and did not result in counts necessary to produce an AUC estimate. In these years maximum likelihood estimates were used to produce estimates as was the case in 2004 (3,500). A Chinook salmon MR program was initiated on the Dean River in 2006 to generate expansion factors for converting the current spawner indices (AUC estimates from helicopter flights) into estimates of total escapement. The preliminary estimate of escapement based on the MR program was 5,478 in 2006 compared to the maximum likelihood estimate of 3,689 . For the purposes of this report however, the index of escapement is reported in the figures. In line with this methodology, an AUC estimate of 1,600 Chinook salmon was derived for the Dean River in 2010.

Escapement Goal Basis: There is no CTC accepted escapement goal for this stock. Biologically-based goals for this complex of Chinook salmon spawning populations have not yet been developed. Future assessments will partition this large aggregate into stocks by run timing, life history and geographic areas.

Agency Comments: Based on the large contribution of the Dean River to Area 8 escapements and due to gaps in the escapement data for other streams in Area 8, the Dean River alone is used to represent stock trends in Area 8. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for the Dean River, but estimates of total escapement are needed to make them effective.

Escapement Methodology: The Rivers Inlet escapement indicator aggregate consists of the Wannock Conservation Unit (CU) and the Rivers Inlet CU, each recognized under Canada’s Wild Salmon Policy. The largest contributor to the production of the Rivers Inlet combined
index is the Wannock CU, which represents an average of $76 \%$ of the production for this index over the past ten years. More recently, however, this has risen to an average of $91 \%$ for the period of 2007-2010.Wannock Chinook salmon have been shown to be distinct from other populations in the central coast of British Columbia based on salmon microsatellite DNA analysis. This ocean-type stock exhibits fall run timing and is renowned for its large size at return. The Wannock River drains Owikeno Lake, is about six kilometers long, and is wide and turbid. Assessment methodologies consist of an annual carcass recovery program which provides an index of abundance. Index estimates are derived by expanding the number of carcasses pitched based on a number of factors which include river clarity, river height, and recovery effort. Estimates are somewhat subjective and a program to calibrate this index with a statistically-derived population estimate using traditional MR experiments was conducted from 1991-1994. Results suggest the index of escapement is an underestimate of the true Wannock population. Indices have ranged from 500 in 1999 to 8,000 in 1993. From 1990-2010, the average index was 3,700 .

Escapement Goal Basis: The low escapement recorded in 1999 led to restrictions in the terminal Rivers Inlet sport fishery which is believed to be the largest single harvester of Wannock Chinook salmon. These sport fishery restrictions, which remain in effect, include a terminal closed area, a downrigger ban, and a restriction on the use of attractors. There is no current CTC accepted escapement goal for the Wannock or Chuckwalla/Killbella stocks. Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for these stocks, but estimates of total escapement are needed to make them effective. Also, it is unclear if the habitat-based escapement goals are reasonable given the unique characteristics of the Wannock River (Parken et al. 2006).

Agency Comments: The remaining Chinook salmon populations in Rivers Inlet have been grouped into a unique CU based on differing genetic and life history traits. These stocks which are spring-run, smaller at return, and stream-type, are found in the Rivers Inlet CU. This CU includes the Owikeno Lake tributary stocks (Amback, Ashlulm, Dallery, Neechanz, Sheemahant, Tzeo and Washwash, as well as the Clyack River which flows into Moses Inlet and the Chuckwalla and Kilbella Rivers which flow directly into Rivers Inlet). Only Chuckwalla and Kilbella Chinook salmon stocks are included in the Rivers Inlet combined index as they are assessed annually and make up the majority of production for this stock group. Escapements for the Chuckwalla and Kilbella are estimated using Area-Under-The-Curve methodology which is typically based on a series of four helicopter flights spaced over the Chinook salmon spawning period. Enhancement efforts were conducted on these systems from 1990 to1998 and the corresponding production can be observed in the escapement graph for the years 1994 through to 2003. Estimated returns for the Chuckwalla and Kilbella combined averaged 1300 Chinook salmon during the period of enhanced returns. Subsequent returns during the post-enhancement period of 2004 through to 2010 have decreased to an average of 760 and the estimated combined return in 2010 was one of the lowest in recent history at 225 . It is unclear if this CU is merely returning to pre-enhancement levels or is experiencing an unrelated decline. Given the significant differences in life history and genetic makeup between stocks within the Rivers Inlet combined index it is advisable to assess them on an individually. There is no CTC accepted escapement goal for either of the Chinook salmon CUs within the Rivers Inlet combined index.

### 2.4.2.3 West Coast Vancouver Island and Georgia Strait

Escapement Methodology: The WCVI index represents the sum of escapements for six rivers (Marble, Tahsis, Burman, Artlish, Kaouk, and Tahsish), which were chosen to provide an 'index' of escapement for wild WCVI stocks in general. These stocks were chosen based on historical consistency of data quality. CDFO has developed a 14 -stream expanded index which includes escapements to the six stream index plus the following WCVI streams: Colonial/Cayegle Creeks (Area 26), Leiner (Area 25), Megin, Bedwell/Ursus, Moyeha (Area 24) and Sarita, Nahmint (Area 23), and San Juan (Area 21). In 2005, the Colonial/Cayegle escapement was not available, and was therefore not included in the 14 -stream index. Since 2007, a MR program has been conducted on the Burman River, a SSP (Section 3.1.3.2), in addition to the regular swim and foot surveys. However, the escapement estimate used for the index followed the same methodology since 2005.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: Habitat-based estimates of $\mathrm{S}_{\mathrm{MSY}}$ and other stock-recruitment reference points are available for these stocks (Parken et al. 2006), but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements as part of the SSPs at the Burman, Moyeha, and Kaouk Rivers (Section 3.1.3). WCVI Chinook salmon have remained below the agency goal for these streams since 1999 despite terminal fishing closures in effect in Areas 24-26 in July each year and efforts to conserve WCVI Chinook salmon in Canadian fisheries. Escapements to all non-enhanced Clayoquot Sound and Kyuquot Sound Chinook salmon streams in the indices all remain below 500 fish.

Escapement Methodology: The Upper Strait of Georgia (UGS) stock index consists of four rivers (Klinaklini, Kakweiken, Wakeman, Kingcome) in Johnstone Strait mainland inlets and the Nimpkish River on northeast Vancouver Island. The accuracy of escapement estimates in the mainland inlet systems is likely poor due to low visibility of glacial systems, remote access, and timing of surveys. Escapement estimates have primarily been based on aerial counts targeting other salmon species, which may not coincide with the main spawning period for Chinook salmon. Swim surveys and stream walks have been conducted in the Nimpkish River. A fish wheel program occurred on the Klinaklini River from 1997 to 2004. Based on the portion of the assessment program that continued in 2005, estimated abundance in 2005 was assumed to be the same as in 2004. Since 2006, the accuracy of the escapement estimate for the Klinaklini is considered to be very poor. Consequently, escapement for this stock was not included in the 2006 or 2007 index. No fish were observed in the Kakweiken River in 2006 or 2007.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: Assessment of stock status is highly uncertain and the escapement time series requires standardization to better represent this stock group in the PSC Chinook Model. Differences in ocean distributions, run timing, and life history indicate that future assessments should separate the stock group into CUs. Habitat-based estimates of $\mathrm{S}_{\text {MSy }}$ and other stockrecruitment reference points are available for Salmon and Klinaklini Rivers, but estimates of total escapement are needed to make them effective.

Escapement Methodology: The LGS rivers are monitored for naturally spawning fall Chinook salmon escapement are the Cowichan and Nanaimo Rivers. Total Chinook salmon returns to the Cowichan and Nanaimo Rivers have been estimated since 1975. Prior to 1988, escapement estimates from the Cowichan River were derived from swim and aerial surveys. This approach was also used for the Nanaimo River prior to 1995. Since 1988 a counting fence has been used in the Cowichan River, and since 1995 carcass MR surveys have been used in the Nanaimo River. Since 2005, AUC estimates have been used in the Nanaimo River and a tagging study was used to determine survey life in 2006.

Escapement Goal Basis: An escapement goal of 6,500 for the Cowichan River was accepted by the CTC in 2005. There is currently no CTC accepted escapement goal for the Nanaimo, however habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for the Nanaimo River (Parken et al. 2006), and spawner abundances have been below $\mathrm{S}_{\mathrm{MSY}}$ abundance recently.

Agency Comments: The Cowichan Chinook salmon stock showed considerable increase in 1995 and 1996, followed by a rapid decline to conservation concern levels. Significant fishery management actions are used to reduce exploitation levels on the LGS Chinook salmon stock group.

### 2.4.2.4 Fraser River

The Fraser River watershed is the largest Canadian producer of Chinook salmon. Fraser Chinook salmon consist of many local populations as described in CTC (2002b).

Much of the knowledge about the status of Fraser Chinook salmon is based on spawner escapement data. Most data are from visual surveys, which are generally biased low, although many estimates are considered to be reasonably precise. Visual survey data are generated from aerial surveys and the escapement estimate is usually obtained by dividing the peak count by 0.65 (Farwell et al. 1999). The CDFO continues to evaluate the appropriateness of this expansion
factor and AUC methodology through calibration studies and the SSPs (Section 3.1.4). Counting fences and MR projects exist for some systems, although most of the time series of escapement data from these projects are relatively short.

For populations other than the Harrison River, habitat-based models are being developed to estimate spawning capacity and spawner abundance producing maximum sustained yield. This habitat-based assessment will initially focus on predictive models based on Chinook salmon stock-recruitment relationships, although other habitat-based approaches will also be considered.

Escapement Methodology: The Fraser Spring-Run Age 1.3 aggregate includes the Upper Pitt River and Birkenhead River stocks in the Lower Fraser, and the spring-run stocks of the Mid and Upper Fraser, North Thompson, and South Thompson, but excluding those of the Lower Thompson tributaries (CTC 2002b). Escapements declined again in 2010, and also failed to exceed the parental brood escapement levels in 2005. Escapement to the aggregate was estimated at 18,061 in 2010; which was roughly $82 \%$ of the main brood year escapement in 2005.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this aggregate.

Agency Comments: Habitat-based estimates of $\mathrm{S}_{\text {MSY }}$ and other stock-recruitment reference points are available for this stock group, but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR and electronic resistivity counter methods.

Escapement Methodology: The Fraser Spring-Run Age 1.2 aggregate includes six smaller body size populations that spawn in the Lower Thompson River tributaries, Louis Creek of the North Thompson and the spring-run fish of Bessette Creek in the South Thompson (CTC 2002b). Escapements to the aggregate improved in 2010, and approximately equaled those of the 2006 parental brood escapement. The estimated aggregate escapement was 6,576 of which escapements to the Nicola $(4,711)$ were the principal contributor.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this aggregate.

Agency Comments: Habitat-based estimates of $\mathrm{S}_{\text {mSy }}$ and other stock-recruitment reference points are available for this stock group (Parken et al. 2006), but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR and electronic resistivity counter methods.

Escapement Methodology: The Fraser Summer-Run Age 1.3 aggregate includes 10 populations that spawn in large rivers, mostly below the outlets of large lakes. These include the Nechako River Chilko and Quesnel Rivers in the mid Fraser and the Clearwater River in the North Thompson watershed (CTC 2002b). Escapement surveys of the Stuart River and North Thompson River were discontinued in 2004 due to unreliable counting conditions. Escapements in 2010 declined over escapements in 2009; and were marginally below those of the parental brood year escapements in 2005. Aggregate escapement was estimated at 18,229, roughly $95 \%$ the 2005 parental brood escapement in 2005.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for the aggregate.

Agency Comments: Habitat-based estimates of $\mathrm{S}_{\mathrm{MSY}}$ and other stock-recruitment reference points are available for this stock group, but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by developing factors that calibrate the visual survey indices to total escapements estimated by MR and area-under-thecurve methods.

$\begin{array}{lllllllllllllllllll}75 & 77 & 79 & 81 & 83 & 85 & 87 & 89 & 91 & 93 & 95 & 97 & 99 & 01 & 03 & 05 & 07 & 09\end{array}$
Escapement Methodology: The Fraser Summer-Run Age 0.3 aggregate includes six populations spawning in the South Thompson watershed upstream of Kamloops and one in the lower Fraser. These include the Middle Shuswap, Lower Shuswap, Lower Adams, Little River and the South Thompson River mainstem, in the BC interior, and Maria Slough in the lower Fraser (CTC 2002b). Escapements to the Summer Run Age 0.3 aggregate attained new record levels in 2010, and increased substantially over those observed in 2009. The 2010 aggregate escapement of 157,274 represents approximately 105\% of the main parental brood year escapements in 2006.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for the aggregate.
Agency Comments: Habitat-based estimates of $\mathrm{S}_{\mathrm{MSY}}$ and other stock-recruitment reference points are available for this stock group (Parken et al. 2006), but estimates of total escapement are needed to make them effective. Work is currently underway to estimate total escapements by
developing factors that calibrate the visual survey indices to total escapements estimated by MR methods and novel methods via the SSP.

Fraser Late - Harrison River

Escapement Methodology: The Fraser late stock is dominated by fall returning Harrison-origin Chinook salmon that includes natural spawners in the Harrison River and Harrison-origin fish that were introduced to the Chilliwack River. Since 1984, MR studies have been conducted annually on the Harrison River to obtain reliable estimates of spawning escapements. Estimates of fall Chinook salmon escapement to the Chilliwack River are based on a procedure long established by the Chilliwack Hatchery staff for expanding the number of carcasses counted in standardized reaches of the river. Spawning escapements to the Harrison River in 2010 were estimated to be 103,515 adult Chinook salmon, and 10,546 jacks. Total fall Chinook salmon escapements to the Chilliwack River were estimated to be 74,947 adults and 9,975 jacks.

Escapement Goal Basis: Due to their natural abundance and importance in numerous British Columbia and Washington State fisheries, Harrison River Chinook salmon were designated as an escapement indicator stock (i.e., 'key stream' indicator) to aid in fulfilling commitments under the 1985 Pacific Salmon Treaty. In 1986, an interim escapement goal for Harrison River

Chinook salmon was established at 241,700 fish, based on doubling of the escapement estimate obtained from a MR program in 1984. In 2001, an escapement goal range was developed for Harrison Chinook salmon using a Ricker stock-recruit approach and is described in CTC (2002b). The escapement goal range that was proposed was $75,100-98,500$ with the upper bound equal to the upper $75 \%$ confidence limit derived from a bootstrap procedure. This range was reviewed and accepted by the CTC. Estimated spawning escapements in the Harrison have exceeded this escapement goal range in nine years from 1984 to the present. They have fluctuated substantially with no apparent trend in the time series.

Agency Comments: Chinook salmon originating in the Harrison River are white-fleshed fish that return to spawn during the fall. They are unusual in that fry migrate into the lower Fraser River and estuary shortly after emergence. This stock spends 2-4 years in the coastal marine environment before returning to spawn. The Harrison River stock is one of the largest naturally spawning Chinook salmon populations in the world and makes important contributions to fisheries in the Strait of Georgia, southern BC, and Washington State.

### 2.4.3 Coastal Washington, Columbia River, and Coastal Oregon Stocks

### 2.4.3.1 Coastal Washington

The PSC escapement indicator stocks in Washington, Oregon, and Idaho are separated into five regional groups: Puget Sound, Washington Coastal, Columbia River, North Oregon Coastal, and Mid Oregon Coastal. The indicator stocks include a variety of run timings and ocean distributions. Some of these indictor stocks are components in the different stock groups listed in Attachment I-IV tables in the treaty.

Biologically-based escapement goals have been reviewed and accepted by the CTC for three fall stocks (Queets, Quillayute, Hoh as part of the Washington Coastal Fall Natural Stock Group), two Spring/summer stocks (Queets, Hoh), four Columbia River stocks (Lewis, Upriver Brights and Deschutes as the Columbia River Fall Stock Group and the Columbia River Summer Stock Group), and three Oregon coastal stocks (Nehalem, Siletz and Siuslaw as the Far North Migrating Oregon Coastal Falls Stock Group).

Escapement Methodology: The Nooksack River drains into Puget Sound near Bellingham. The Nooksack spring Chinook salmon stock includes early-timed populations returning to the North and South forks of the Nooksack River. Estimates of the escapement in the South Fork have traditionally been based on the number of redds observed prior to the first of October expanded by 2.5 redds per spawner. Since 1999, this estimate has been further refined by separating hatchery-origin strays (North/Middle Fork and summer/fall Chinook salmon) based on CWTs, otolith marks or adipose fin clips, and also by assigning the natural origin spawners to the South Fork, North/Middle Fork and summer/fall hatchery stocks. The latter step is based on the expansion of the microsatellite DNA stock assignment of carcasses collected through the first week of October to apply to the total estimated natural origin spawners. The majority of the run is composed of hatchery-origin returns from the supplementation program. During 1999-2008, only $15 \%$ of the escapement in the North Fork and $50 \%$ of the escapement in the South Fork was composed of natural origin fish (CCMP 2010). In 2010, the natural escapement estimate was 2,044 for the North Fork and 377 for the South Fork.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: The state-tribal escapement goal established for this Chinook salmon management unit is 4,000 spawners as an upper management threshold (UMT) and a low abundance threshold (LAT) of 2,000 natural origin fish (CCMP 2010). The UMT as established by the state-tribal managers is generally considered as the adult (age 3+) escapement level associated with maximum sustained catch. The LAT is the escapement level below which dramatic declines in long term productivity could occur. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a ceiling exploitation rate rather than for a UMT or LAT escapement. The stock achieved the LAT in 2010.

Escapement Methodology: The Skagit River drains into northern Puget Sound near Mount
Vernon, and is the largest drainage basin in Puget Sound. The Skagit spring Chinook salmon stock includes early-timed populations returning to the Upper Sauk, Cascade, and Suiattle Rivers. Due to changes in spawning index areas, beginning in 1992 for the Cascade stock and 1994 for the Sauk and Suiattle stocks, escapements are not directly comparable to previous numbers. In the Upper Sauk, redds are counted from RM 21.2-39.7 (Darrington to Forks), in the North Fork Sauk from the mouth to Falls, and in the South Fork Sauk (RM 0-2.5). This method replaced peak live and dead count approach in 1994. A redd life value of 30.2 days is used (avg of foot survey-based estimate $=22.9$ days and AUC back calculated $=37.5$ days). In the Cascade River, redds are counted in the mainstem upstream of RM 7.8 and in the lower north fork and south fork, and Found, Kindy, and Sonny Boy creeks Two helicopter flights occur over RM 7.8-18.6, and 5 foot surveys. In the Suiattle basin, redds are counted in mainstem Suiattle, and in Big, Tenas, Straight, Circle, Buck, Lime, Downey, Sulphur, and Milk creeks. Prior to 1994, peak live and dead fish counts in Big, Tenas, Buck, and Sulphur were used. The 2010 escapement estimate was 1,036 natural spawners.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.

Agency Comments: The current UMT used by the state and tribal co-managers for the Skagit spring Chinook salmon management unit is 2,000 with a LAT of 576 (CCMP 2010). Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a total exploitation rate ceiling rather than for a UMT or LAT escapement.

Escapement Methodology: The Skagit River summer/fall Chinook salmon stock includes the Upper Skagit summer, Sauk summer, and Lower Skagit fall run populations. Escapement of Skagit summer/fall Chinook salmon was estimated using expansion of redd counts from helicopter surveys of mainstem areas and foot surveys of smaller tributaries. The counts are expanded by the area-under-the-curve method (Smith and Castle 1994). This method assumes a 21-day redd life and 2.5 adult spawners for each estimated redd. The estimate is then reduced by $5 \%$ to account for "false" redds counted during aerial surveys. The 2010 escapement estimate was 8,037 . The terminal run estimate was 9,060 . The methodology used to calculate the terminal run in the time series was modified in 2011 to include freshwater sport catch in the total return.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: The UMT used by the state-tribal co-managers for the Skagit summer/fall Chinook salmon management unit is 14,500 based on a recent assessment of freshwater productivity and accounting for variability and biases in management error (CCMP 2010). The LAT is 4,800 spawners. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a total exploitation rate rather than for a UMT or LAT escapement. In years when the UMT is expected to be exceeded, terminal fisheries can be expanded subject to the overall ceiling exploitation rate.

Escapement Methodology: The Stillaguamish River drains into northern Puget Sound between Everett and Mount Vernon. The Stillaguamish Chinook salmon stock includes a run of summertimed Chinook salmon in the North Fork of the Stillaguamish River and a much smaller number of fall fish in the South Fork of the Stillaguamish River and mainstem of the Stillaguamish River. Escapement estimates for Stillaguamish Chinook salmon were based on redd-count expansions, assuming a 21-day redd life. The North Fork of the Stillaguamish River is surveyed more extensively, with one to three aerial surveys and AUC redd estimates. The escapement estimates for the South Fork of the Stillaguamish River uses a peak redd count and assumes 2.5 fish per redd. Boulder and Squire Creeks on the North Fork of the Stillaguamish River and Jim Creek on the South Fork of the Stillaguamish River are also surveyed. Spawning escapement estimates of fall Chinook salmon may be biased low due to incomplete redd counts using visual sampling methods. Total natural spawning escapement in 2010 was estimated at783 fish. The methodology used to calculate the terminal run in the time series was modified in 2011 to include freshwater sport catch in the total return.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: State-tribal co-managers have established a UMT for this management unit of 900 natural origin spawners (600-North Fork of the Stillaguamish River and 300-South Fork of the Stillaguamish River and mainstem) with a LAT of 700 (CCMP 2010). The summer Chinook salmon supplementation program, which collects brood stock from the North Fork of the Stillaguamish River return, was initiated in 1986 as a Pacific Salmon Treaty indicator stock program, and its current objective is to release 200,000 tagged fingerling smolts per year. Most releases are into the North Fork of the Stillaguamish River, via acclimation sites; relatively small numbers of smolts have been released into the South Fork of the Stillaguamish River. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a ceiling exploitation rate rather than for a UMT or LAT escapement.

Escapement Methodology: The Snohomish River is located in northern Puget Sound near Everett. The Snohomish Chinook salmon stock includes the Skykomish and Snoqualmie summer/fall run populations. Skykomish Chinook salmon spawn in the mainstem of the Skykomish River, and its tributaries including the Wallace and Sultan Rivers, in Bridal Veil Creek, the South Fork of the Skykomish River between RM 49.6 and RM 51.1 and above Sunset Falls (fish have been transported around the falls since 1958), and the North Fork of the Skykomish River up to Bear Creek Falls (RM 13.1). Snoqualmie Chinook salmon spawn in the Snoqualmie River and its tributaries, including the Tolt River, Raging River, and Tokul Creek. Escapement was estimated using expansion of redd counts conducted by a combination of helicopter, float, and foot surveys, and from fish counts at the Sunset Falls fishway. The 2010 escapement was estimated at 4,299 natural spawners. The methodology used to calculate the terminal run in the time series was modified in 2011 to include freshwater sport catch in the total return.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: The state-tribal co-managers have a UMT for this stock of 4,600 natural origin spawners (CCMP 2010). The LAT for Snohomish summer/fall Chinook salmon is 2,800 fish. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a ceiling exploitation rate rather than for a UMT or LAT escapement.

Escapement Methodology: The Lake Washington Chinook salmon stock includes the fall run populations in the Cedar River and in the North Lake Washington tributaries of Bear, Cottage, and Issaquah creeks. Natural spawners in Issaquah Creek that spawn below the Issaquah Hatchery are not included in the graph. It should be noted that although there are no hatchery fish released into the Cedar River, an average of $23 \%$ of the spawners in 2003-08 were adipose clipped from mass-marked hatchery production, presumably from Issaquah Hatchery (CCMP 2010). Escapement in the Cedar River is estimated using expansion of total redd counts. In recent years, estimates of spawner abundance have also been made using redd counts performed over the entirety of the spawning area downstream of Landsburg Dam (CCMP 2010). These data were used to convert previous estimates of escapement within the index reach to estimates of spawner abundance (as would be derived through redd counts) for the entirety of the river (below the dam) using simple linear regression. Escapement to the North Lake Tributaries is estimated using live counts and AUC methods. The 2010 escapement for Lake Washington was 729 spawners, including 80 primarily hatchery origin fish in Bear and Cottage creeks. The methodology used to calculate the terminal run in the time series was modified in 2011 to include freshwater sport catch in the total return.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: A state-tribal interim UMT escapement goal of 1,200 Chinook salmon for an index reach in the Cedar River was established in 1993 based on average escapements in 1965-69. This goal for the index reach was converted to 1,680 Chinook salmon for the entirety of the river downstream of the dam. This number $(1,680)$ reflects a redd-based escapement value consistent with the interim escapement goal derived using AUC methodology. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been for a ceiling exploitation rate rather than for a UMT or LAT escapement in the Cedar River, except when the UMT is expected to be exceeded, some additional fishing in Lake Washington is considered.

Escapement Methodology: The Green River Fall Chinook salmon stock consists of a single population spawning in the mainstem Green River and two of its major tributaries, Newaukum and Soos creeks. Escapement is estimated from redd count expansion method that has varied over the time series by the extent of spawning survey coverage. The method used until about 1996 involved an index area redd count multiplied by 2.6 to estimate total redds then multiplied by 2.5 fish/redd to produce estimated escapement. The 2.6 index to total redd expansion factor was based on a U.S. Fish and Wildlife Service MR study in 1976 and 1977. Since 1996, the survey areas have broadened and the associated expansion factor of 2.6 has been reduced to the point that the redd counts in 2009 have complete spawning reach coverage. The method used in recent years provides natural escapement estimates for the mainstem Green River and Newaukum Creek. Newaukum Creek redds are counted during foot surveys. The mainstem Green River is surveyed by boat and by air. Some parts of the river (i.e. - the Gorge) are only surveyed by air. Boat surveys are generally done once a week, or twice a week in years with a large numbers of pink salmon. One aerial survey is made during the peak of spawning, more if budgets permit. Certain index reaches of the river are surveyed every week by boat to develop a cumulative redd count total for those reaches. These index reaches are distributed throughout the river. Visible redds are counted for the entire floatable part of the river by boat each week and for the entire river by helicopter during the peak. The ratio of visible redds seen by boat to those seen by air (boat surveys assumed to be best) is used to estimate how many redds would be seen by boat in the unfloated reaches. This provides an estimate of how many visible redds exist during the peak of spawning. To get from peak redds to cumulative total redds, the visible redds in the index reaches during the peak are compared to the season total for those index reaches. Different areas of the river have different ratios of peak visible redds to season totals. Expansion of non-index visible redds to season total redds uses the ratio from nearby index reaches of the same general character. The CTC considers these estimates from redd counts as index values rather than estimates of total escapement. Estimates of total escapement from MR studies in 2000-02 funded through the U.S. Letter of Agreement were more than three times higher than the escapement estimate from redd count expansion. There is a large hatchery program in this basin and these fish comprise a large portion of the return. Hatchery fish contribution to the natural escapement ranged from $53 \%$ to $65 \%$ for 2004-07. The escapement in 2010 from redd count expansion was 2,099 Chinook salmon of mixed hatchery and natural origin. The
methodology used to calculate the terminal run in the time series was modified in 2011 to include freshwater sport catch in the total return.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: The state-tribal UMT escapement goal of 5,800 naturally spawning adults is the average of the 1965-1976 escapements (Ames and Phinney 1977). The LAT is 1,800 fish. Since listing in 1999 as threatened under the ESA, annual fishery management for this stock has been on a ceiling exploitation rate in the southern U.S. pre-terminal fisheries and for the UMT in the terminal fisheries.

Escapement Methodology: Hoko River fall Chinook salmon spawn primarily in the mainstem of the Hoko, with limited spawning in larger tributaries. The Makah Tribe and WDFW conduct ground surveys using cumulative redd counts for the mainstem and tributaries found between RM 1.5-21.7, which represents the entire range of spawning habitat utilized by Chinook salmon. Redd counts are multiplied by 2.5 adults/redd. There are 10 mainstem reaches plus 13 tributary reaches, including Little Hoko, and Browne's, Herman, NF Herman, Ellis, Bear, and Cub (all upper mainstem tributaries). The tribe also surveys the mainstem Sekiu and Carpenter, SF Carpenter, Sunnybrook, and unnamed creeks 19.0215, 19.0216, and 19.0218. Brood stock collected from the spawning grounds for the supplementation program are included in the escapement estimate. In 2010, total natural spawning escapement was estimated to be 239.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: The UMT escapement goal established by state and tribal co-managers is 850 naturally spawning adults. This goal was developed as a proxy for the spawning escapement for MSY. The escapement goal was calculated using a habitat based approach rather than a stock-recruitment analysis by estimating the amount of available spawning habitat, then expanded utilizing assumed optimal redds per mile and fish per redd values (Ames and Phinney 1977).

Escapement Methodology: Escapement estimates are based on redd counts in index areas and from supplemental surveys on the Bogachiel River, mainstem Calawah, and in the North Fork Calawah and Sitkum Rivers. This has been used consistently in the Quillayute River System since the 1970's. Surveys are conducted by foot, raft, drift boat and helicopter. Surveys in index areas are examined either weekly or bi-weekly as conditions allow. Supplemental surveys are done once a season during the peak spawning period. Redd counts from these supplemental surveys are then expanded by the index surveys to estimate redd construction within the supplemental survey areas for the entire season. Using an appropriate redds per mile assignment, the information from index and supplemental surveys is then applied to other streams and segments that have historically had fish presence, but were not surveyed. These areas comprise the Quillayute River system "stream mileage base" that is consistently calculated to estimate escapement numbers. The number of redds is multiplied by 2.5 to estimate fish escapement. The 2010 escapement estimate for summer Chinook salmon was 659 from a terminal run of 828.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock.
Agency Comments: The state-tribal management goal for this stock is 1,200 adults and jacks combined (PFMC 2003).

Escapement Methodology: Escapement estimates are based on redd counts in index areas and from supplemental surveys on the Bogachiel, Sol Duc, Dickey, Calawah Rivers and several other smaller tributaries in the basin. This has been used consistently in the Quillayute River System since the 1970 's. Surveys are conducted by foot, raft, drift boat and helicopter. Surveys in index areas are examined either weekly or bi-weekly as conditions allow. Supplemental surveys are done once a season during the peak spawning period. Redd counts from these supplemental surveys are then expanded by the index surveys to estimate redd construction within the supplemental survey areas for the entire season. Using an appropriate redds per mile assignment, the information from index and supplemental surveys is then applied to other streams and segments that have historically had fish presence, but were not surveyed. These areas comprise the Quillayute River system "stream mileage base" that is consistently calculated to estimate escapement numbers. The number of redds is multiplied by 2.5 to estimate fish escapement. The 2010 escapement estimate was 4,635, with a total terminal run estimate of 6,431.

Escapement Goal Basis: The CTC approved in 2004 the escapement goal for Quillayute fall Chinook salmon of 3,000 natural spawners based on spawner-recruit analysis developed by Cooney (1984) and QDNR (1982).

Agency Comments: Terminal fisheries are managed for a harvest rate of $40 \%$, with an escapement floor of 3,000 fish (PFMC 2003). This objective is designed to actively probe at and above estimates of escapements that produce maximum sustained harvest (MSH), while minimizing potential detrimental effects of existing fisheries. Stock production analyses of spawning escapements from 1968-1982 were used to determine the initial escapement floor.

Escapement Methodology: Escapement is estimated from redd counts in index areas and from supplemental surveys in the mainstem and South Fork Hoh River and in Winfield, Owl, and Mount Tom creeks. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. The 2010 escapement estimate and total run size were 828 and 861 respectively.

Escapement Goal Basis: Escapement floor policy of 900 for the Hoh spring/summer Chinook salmon was developed by Cooney (1984) and QDNR (1982), based on spawner-recruit analyses, and was accepted by the CTC in 2004.

Agency Comments: Similar to many of the other Washington coastal stocks, Hoh River spring/summer escapements have been relatively stable except for much larger returns in 1988, 1989, and 1990. The terminal return for this stock declined from 1997 to 2000, had rebounded in 2001 before declining again since 2005. Terminal fisheries are managed to harvest $31 \%$ of the river run, with an escapement floor of 900 fish (PFMC 2003). This objective is designed to allow a wide range of spawner escapements from which to eventually develop an MSY objective or proxy while protecting the long-term productivity of the stock. Stock production analysis of spawning escapement for brood years 1969-1976 was utilized to determine the initial escapement floor.

Escapement Methodology: Escapement is estimated from redd counts in index areas and supplemental surveys in the mainstem and South Fork Hoh River and in tributaries with spawning habitat. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. The natural escapement estimates for Hoh River fall Chinook salmon include fish taken for brood stock. The 2010 escapement estimate was 2,599 fish. Terminal run estimate was 2,941 .

Escapement Goal Basis: The escapement floor of 1,200 for the Hoh fall Chinook was developed by Cooney (1984) and QDNR (1982), based on spawner-recruit analyses, and was accepted by the CTC in 2004 as the escapement goal.

Agency Comments: The state-tribal management plan for this stock includes a harvest rate of $40 \%$ of the terminal run, with an escapement floor of 1,200 spawners (PFMC 2003). This objective is designed to actively probe at and above estimates of the escapements that produce MSH, while minimizing potential detrimental effects of existing fisheries. Stock production analyses of spawning escapements from 1968-1982 were utilized to determine the initial escapement floor.

Escapement Methodology: Escapement is estimated from redd counts during August 15 through October 15 for spring/summer Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. The 2010 estimate of escapement and terminal return was 382.

Escapement Goal Basis: Escapement floor policy of 700 for Queets spring/summer Chinook salmon was developed by Cooney (1984) and QDNR (1982), based on spawner-recruit analyses, and was accepted by the CTC in 2004 as the escapement goal. Stock production analysis of spawning escapements for brood years 1969-1976 were used to determine the initial escapement floor.

Agency Comments: Terminal fisheries are managed by the state and tribes to harvest $30 \%$ of the river run size, with an escapement floor of 700 fish (PFMC 2003). This objective is designed to actively probe at and above the estimates of escapement that produce MSH. Since 1990, terminal fisheries have had minimal impact on this stock as returns to the river have rarely exceeded the escapement floor. Since 2000, sport anglers have been required to release all Chinook salmon during the summer, and tribal fisheries have been limited to one tribal netting day for ceremonial and subsistence purposes.

Escapement Methodology: Escapement is estimated from redd counts during October 15 through December 1 for fall Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. For Queets River fall Chinook salmon, the 2010 escapement was 4,022 and the terminal run was 6,032 .

Escapement Goal Basis: the escapement floor policy of 2,500 for the Queets fall Chinook was developed by Cooney (1984) and QDNR (1982), and was based on spawner-recruit analyses, and was accepted by the CTC in 2004 as the escapement goal.

Agency Comments: Terminal fisheries are managed by the state and tribes to harvest $40 \%$ of the river return, with an escapement floor of 2,500 spawners (PFMC 2003). This objective is designed to actively probe at and above estimates of the escapements that produce MSH. Stock production analyses of spawning escapements from 1967-1982 were used to determine the initial escapement floor.

Escapement Methodology: Escapement is estimated by redd counts during August 15 through October 15 for spring/summer Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. The 2010 escapement was 3,497 Chinook salmon and the terminal run 3,704.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: The natural spawning escapement goal established by the state-tribal comanagers for Grays Harbor spring Chinook salmon is 1,400 adult fish (PFMC 2003). This single targeted goal was developed as a MSY proxy. This objective was derived from actual spawning data from the mid- to late 1970s, expanded to include additional habitat not covered by spawner surveys.

Escapement Methodology: Escapement is estimated from redd counts during October 15 through December 1 for fall Chinook salmon. Surveys are conducted by foot, boat, and helicopter. Intensively monitored index reaches are surveyed each week where surveyors record total new and visible redds observed each week. Cumulative redd counts for each index reach represents the total spawner abundance for that particular spawning area. Weekly visible redd counts in index reaches are used to estimate spawning timing curves by calculating the proportion of season cumulative redds that are visible on each weekly survey date. Extensive surveys are also conducted in non-intensively monitored stream areas utilized by spawning Chinook salmon. These extensive reaches encompass areas too large or remote to intensively monitor throughout the season. Extensive surveys are timed as close as possible to peak spawning activity. Extensive reach spawner abundance estimates are derived using index timing curves. For areas with suitable habitat but not regularly surveyed, redd densities (cumulative redds/river mile) from surveyed reaches with similar habitat-type are used to estimate escapement into these reaches of known stream length. The total natural spawning escapement is calculated assuming 2.5 fish/redd. The 2010 escapement was 14,531 spawners from a terminal run of 18,802 Chinook salmon.

Escapement Goal Basis: There is currently no CTC accepted escapement goal for this stock group.

Agency Comments: The state-tribal escapement goal for Grays Harbor fall Chinook salmon is 14,600 spawners to the combined Chehalis and Humptulips Rivers (PFMC 2003). This single targeted goal was developed as an MSY proxy. The objective represents assumed optimal spawner density based on estimated available habitat.

### 2.4.3.2 Columbia River

Escapement Methodology: The Columbia Upriver Spring Chinook salmon stock is an aggregate of Upper Columbia spring Chinook salmon and Snake River spring/summer Chinook salmon. Historically, the Bonneville run through June 1 was used in assessments, but the date was changed to June 15 to include the Snake River spring/summer Chinook salmon, which were listed under the ESA in 1992 and pass Bonneville Dam in that time period, so the ESA listed stock could be managed under a more restrictive harvest rate. The escapement in the graph was calculated as the dam count at Bonneville Dam from January 1 through June 15 minus all harvests and incidental mortalities above Bonneville Dam, multiplied by the estimated proportion that spawn naturally, according to the Columbia River Technical Advisory Committee (CTAC) run reconstructions prepared for the biological assessment under the ESA. The interim management goal for the Columbia River Fish Management Plan (CRFMP) for Columbia River Springs was 115,000 hatchery and wild adult Chinook salmon counted at Bonneville Dam and 25,000 naturally-produced plus 10,000 hatchery-produced adults counted at Lower Granite Dam (CRFMP 1988). Under the 2008-2017 U.S. v OR Management Agreement, fishery impacts on natural origin fish are managed using a harvest rate schedule based on expected river mouth abundance.

Escapement Goal Basis: This stock is not managed for an escapement goal. It is managed for an abundance-based harvest rate schedule ranging from $5.5 \%$ to $14.3 \%$.

Agency Comments: The 2008-2017 U.S. v OR Management Agreement (MA) provides for a minimum annual mainstem treaty Indian Ceremonial and Subsistence entitlement to the Columbia River treaty tribes of 10,000 spring and summer Chinook salmon. Fisheries are managed according to the catch rate schedule in Table A1 of the 2008-2017 MA, with allowable impact rates dependant on total upriver spring Chinook salmon run size. Beginning in 2010, modifications to Table A1 were implemented requiring non-Indian fisheries to meet catch balance provisions in the MA for upriver spring Chinook salmon. Under these provisions, non-Indian fisheries are managed to remain within ESA impacts, and to not exceed the TAC available for treaty fisheries. Non-Indian fisheries in 2010 were restricted to no more than $70 \%$ of the available catch specified for treaty fisheries at the preseason forecasted run size for use prior to a run size update.

Escapement Methodology: The escapements graphed above are the Bonneville summer Chinook salmon count beginning June 15 minus Zone 6 and upper Columbia catches and incidental mortalities, multiplied by the proportion of the run returning to the Upper Columbia (Priest Rapids dam count as a proportion of the sum of the Priest Rapids and the largest Snake River dam counts), multiplied by the proportion of non-harvested summer Chinook salmon crossing Bonneville that spawned naturally (as calculated by the CTAC run reconstruction). Terminal run is calculated as the Bonneville run plus the catches and incidental mortalities below Bonneville, multiplied by the same two proportions (proportion Columbia and proportion naturally spawning). Incidental mortalities were subtracted, as were additional catches by the Colville and Wanapum tribes. In 2009, CTAC began using counts at Rock Island to calculate summer Chinook salmon conversion rates, rather than Priest Rapids dam counts, so the entire time series of conversion rates changed.

Escapement Goal Basis: The CTC (1999) developed an interim biologically-based MSY escapement goal of 17,857 naturally spawning upper-Columbia summer Chinook salmon past Bonneville Dam based on PSC Chinook salmon model data. The model data used to develop the escapement goal are different than the actual escapement estimates graphed above, and thus may not be directly comparable. A revised goal using actual escapement data was developed and reviewed by the CTC in 2008 and resulted in a similar goal, but modifications to the analysis were requested and no action was taken.

Agency Comments: Columbia River summer Chinook salmon fisheries occur from June 16 through July 31, according to a catch rate schedule based on expected river mouth abundance. The schedule is provided in Table A2 of the 2008-2017 U.S. v OR MA. In addition, upper Columbia River summer Chinook salmon are managed for a goal of 29,000 hatchery and natural origin adults, as measured at the Columbia River mouth. This management goal is based on an interim combined spawning escapement goal of 20,000 hatchery and natural adults, including the following three components: 13,500 Wenatchee/Entiat/Chelan natural fish, 3,500 Methow/Okanogan natural fish and 3,000 hatchery fish.

Escapement Methodology: Escapement estimates are calculated as the McNary Dam count minus Hanford Reach adult sport catch, minus brood stock taken by Priest Rapids, Ringold and Snake River hatcheries.

Escapement Goal Basis: The CTC agreed escapement goal for the Columbia River Upriver Bright Chinook salmon is 40,000 naturally spawning fish past McNary dam based on stockrecruitment analyses.

Agency Comments: Under the 2008-2017 U.S. v OR Management Agreement, the minimum combined Columbia River and Snake River upriver bright management goal at McNary Dam is 60,000 adult fall Chinook salmon, which includes both hatchery and natural production for all areas above McNary Dam. The Parties also agreed to 43,500 as the minimum Upriver Bright adult escapement to meet the combined Hanford Reach, lower Yakima River, and mainstem Columbia River above Priest Rapids Dam natural spawning goal, as well as the current Priest Rapids Hatchery production (this historically included a minimal run to the Snake River).

Escapement Methodology: Most natural bright fall Chinook salmon production below Bonneville Dam occurs in the North Fork Lewis River. The Lewis River Wild stock is the main component of the Lower River Wild management unit for fall Chinook salmon, which also includes small amounts of wild production from the Cowlitz and Sandy River basins. In this report, the escapements and goal are for the Lewis River component. Annual escapement estimates are obtained by expanding peak counts from weekly counts of live and dead fish in the 6.4 km area below Merwin Dam (rkm 31.4) by a factor of 5.29 (total spawners/peak count) and this factor was derived from a carcass tagging and recapture study performed in 1976 (McIsaac 1990). From 1999-2001, LOA funds were used to conduct a study to estimate and verify the expansion factor. A CWT program for wild fish has been in place since the 1977 brood. Methods of CWT recovery, escapement counting, and expansion of the index area fish counts have been consistent since 1964. All naturally spawning adult fish, both from hatchery and natural production, are included in the escapement. The terminal run is escapement plus the adult sport catch in the Lewis River.

Escapement Goal Basis: The escapement goal of 5,700 fall Chinook salmon in the Lewis River was developed by McIsaac (1990), based on spawner-recruit analysis of the 1964-1982 broods and CWT recoveries from the 1977-1979 broods. This analysis was updated in CTC (1999) based on analysis of brood years 1964-1991 and the goal of 5,700 was reaffirmed and accepted as a biologically based goal.

Agency Comments: Except for 1999, the Lewis River escapements had been above their escapement goal since 1979 until 2007 through 2009, when it was somewhat below goal. In 2010, it was again above goal.

Escapement Methodology: Escapement data are based on a MR estimate for the area above Sherars Falls, expanded for redd counts below Sherars Falls. From 2000 through 2007, Confederated Tribes of the Warm Springs (CTWS) performed an entire river MR experiment to validate the Deschutes River fall Chinook salmon escapement estimates. Results of these MR studies confirm the validity of the historical estimation methodology. For historic years where redd counts were not censured for the entire river, the entire time series of data was updated
based on a comprehensive analysis done by Warm Springs, ODFW and Columbia River Intertribal Fish Commission (CRITFC) staff (Sharma et. al. 2010). An escapement goal was derived from the updated time series and approved by the CTC. The metric reported above is the ODFW MR estimate based on expanding the Sherars Falls MR estimate for redds below Sherars Falls.

Escapement Goal Basis: The CTC agreed escapement goal for Deschutes River fall Chinook salmon is 4,532 fish (Sharma et. al. 2010).

Agency Comments: Deschutes River fall Chinook have been maintained above the escapement goal since 1992.

### 2.4.3.3 Coastal Oregon

### 2.4.3.3.1 Oregon Coastal North Migrating

Currently, only NOC fall Chinook salmon are accounted for in PSC management, while work is underway to include MOC production into the auspices of the PSC regime. The NOC production is bounded by the Necanicum at the northern range through the Siuslaw basin at the southern extent of the NOC. After a period of precipitous declines in escapement during 2007, 2008 and 2009, the NOC stock aggregate has indicated signs of rebuilding to historical averages during the 2010 return year. There are three escapement indicator stocks representing the production of NOC Chinook salmon; the Nehalem, Siletz and Siuslaw stocks. The geographic range of production encompassed by the NOC includes 4 additional major basins, the Tillamook, Nestucca, Yaquina and Alsea. The Tillamook drainage system includes 5 sub-basins including the Kilchis, Miami, Trask, Wilson and Tillamook Rivers. Total estimated spawning escapement in this aggregate has ranged from approximately 39,000 in 2008 to 190,000 in 1988. The ten year (2001-2010) average for the NOC aggregate escapement is about 94,000. Estimated escapement in 2010 was 65,000 . Abundance forecasts are expressed in terms of spawning escapement. Forecasted escapement for 2011 is 78k. Forecasts for this aggregate are based on siblingregression relationships developed for each discrete population, both indicator and non-indicator stocks. The aggregated forecast for the NOC is the sum of the forecasts for the individual basins within the geographic range. These methods were developed in 2008 and are continually refined with each year's additional information. Prior to 2008, the aggregate forecast (and each of the indicator stock's forecasts) was based on a running three year average.

All three NOC escapement indicators did not achieve goal in either 2007 or 2008, and the Nehalem did not attain goal in 2009 or 2010 either, but all three escapement indicator stocks are forecasted to reach their goal in 2011. Recent-year escapements in the southern range of the NOC (Siuslaw, Alsea) have shown encouraging rates of rebound, while their northern counterparts (Nehalem, Tillamook, Nestucca) have displayed a more protracted rebuilding pattern. Escapements in the middle of the NOC area have been observed to be steadily rebuilding between the northern and southern extremes of the aggregate.

Terminal fisheries management action, in concert with AC reductions in AABM fisheries, is contributing to the rebuilding of the NOC escapement. Terminal fisheries restrictions, which
included closure during the 2009 return year in the Nehalem, have been adopted and maintained through the 2010 return year. Many of these restrictions were dropped for the 2011 return year in the southern extent of the geographic aggregate, but most have been retained or extended from those basins north of the Nestucca.

Escapement Methodology: Both directed MR study and historically conducted surveys have been utilized to measure escapement during the past return year. Normative estimates are generated from conducting surveys of peak abundance in historically walked predefined areas of known Chinook salmon spawning habitat within the basin. These observations are then multiplied by an estimate of the total available habitat, an accounting for observer biases, an estimate of the total run encountered during the peak, and an estimate of the bias seen between these predefined surveys and those that are randomly selected.

Escapement Goal Basis: The current point goal of 6,989 spawners was derived by Zhou \& Williams in 1999 and was based on assessments of escapement made through normative survey methodology.

Agency Comments: This stock is being studied by the Sentinel Stock Committee's program to improve escapement estimation. Direct MR adult spawner estimation indicated an escapement of 7,250 Chinook salmon in 2010. Methods comparable to those used to generate the agreed to escapement goal for the Nehalem indicate 2010 escapement of 5,384 adult spawners. This is $77 \%$ of the current escapement goal. This is the fifth consecutive year of this stock's failure to meet its agreed-to escapement goal. Due to continued failures to meet the escapement goal, the terminal sport fall Chinook salmon fishery in the Nehalem was closed in 2009. While a terminal sport fishery was conducted in 2011, significant area closures, daily and seasonal bag restrictions were deployed to assist in the rebuilding of this stock. A creel survey program is planned to estimate catches of this terminal sport fishery in 2011. Based on sibling-regression forecasting methods, the Nehalem is forecasted to meet the escapement goal in 2011. ODFW is engaged in analysis to best use results from recent MR experiments to reconstruct historic estimates from peak-counts observed in normative surveys.

Escapement Methodology: Both directed MR study and historically conducted surveys have been utilized to measure escapement during the past return year. Normative estimates are generated from conducting surveys of peak abundance in historically walked predefined areas of known Chinook salmon spawning habitat within the basin. These observations are then multiplied by an estimate of the total available habitat, an accounting for observer biases, an estimate of the total run encountered during the peak, and an estimate of the bias seen between these predefined surveys and those that are randomly selected.

Escapement Goal Basis: The current point goal of 2,944 spawners was derived by Zhou \& Williams in 2000 and was based on assessments of escapement made through normative survey methodology.

Agency Comments: This stock is being studied under the auspices of the Sentinel Stock Committee's program to improve escapement estimation. Calibration studies were initiated in the 2009 spawning year, thus traditional methods of escapement estimation remain in place until MR experiment based estimation is complete. The MR study of escapement in the Siletz resulted in an independent estimate of 10,985 adult spawners in 2010. Data used to derive the escapement goal are not directly comparable to MR based estimates of escapement. The estimate based upon historically produced habitat expansion methods for 2010 was 4,225 adult fall Chinook salmon. This is the first year since 2006 in which this stock has achieved its escapement goal (with arguable allowance for relative achievement in 2009). Significant terminal area sport fisheries restrictions which included substantial area closures, restrictive daily and seasonal bag limits are believed to have assisted in the achievement of the escapement goal. Area restrictions are planned to continue to provide a conservative management approach until such time as this stock is believed to be recovered from recent precipitous declines in escapement. This stock is forecasted to exceed its escapement goal in 2011.

Escapement Methodology: Both MR study based calibration factors and historically conducted surveys have been utilized to measure escapement during the past return year. Normative estimates are generated from conducting surveys of peak abundance in historically walked predefined areas of known Chinook salmon spawning habitat within the basin. These observations are then multiplied by an estimate of the total available habitat, an accounting for observer biases, an estimate of the total run encountered during the peak, and an estimate of the bias seen between these predefined surveys and those that are randomly selected. A simple ratio comparison between those years of MR based estimates and observations of peak abundance in normative survey areas has been used to generate a "calibrated" estimate.

Escapement Goal Basis: The current point goal of 12,925 spawners was derived in 2000 by Zhou and Williams (2001) and was based on assessments of escapement made through normative survey methodology.

Agency Comments: The estimated spawner abundance in 2010 was 5,160 adult Chinook salmon based on methods employing five years (2002-2006) of peak counts on six standard surveys calibrated to MR escapement estimates. The current escapement goal estimate was based upon available habitat expansion escapement estimates, as used in other basins on the Oregon coast, but these estimates and goals have been obviated through the improvement of estimation techniques based upon MR estimates. Escapement estimates based on habitat expansion methods used to generate the agreed to goal result in an estimated 22,197 adult spawners. Spawner-recruit analysis utilizing the MR based data set is planned for the near future to compare between newer escapement estimation (backcast through historical data-sets) and an escapement goal based upon the same data. This stock is forecast to exceed escapement goal in 2011.

### 2.4.3.3.2 Mid Oregon Coast

The MOC aggregate is currently in proposed status, with analysis and review determining escapement goals for the South Umpqua and Coquille pending. The MOC production is bounded by the Umpqua at the northern range through the Elk basin at the southern extent of the MOC.

After a period of precipitous declines in escapement during 2006 and 2007, the MOC stock aggregate has rebounded to historical averages and above during the 2010 return year. The geographic range of production encompassed by the MOC includes 2 additional major basins, the Coos and Coquille. A smaller contributing basin, the Sixes, is located just north of the proposed exploitation rate indicator stock, the Elk river. Forecasts for this aggregate are based on sibling-regression relationships developed for each discrete population, both indicator and nonindicator stocks. These methods were developed in 2008 and are updated with each year's additional information.

Escapement Methodology: Indices of Chinook salmon spawner abundance in the South Umpqua/Cow creek sub-basin were derived from aerial redd count surveys calibrated to six years of MR study. The aerial surveys are funded by Douglas County and were conducted twice during the spawning season. Aerial redd counts were conducted on the lower 69 miles of the South Umpqua and the lower 60 miles on Cow Creek. These counts cover all mainstem spawning areas for fall Chinook salmon in the South Umpqua Basin. The South Umpqua is broken up into three reaches (Forks to Happy Valley, Happy Valley to Cow Creek, Cow Creek to Milo) and Cow Creek is considered one reach from the confluence with the Umpqua River to Galesville Dam.
Aerial surveys are conducted using a Bell Ranger 3 helicopter; at least two flights are typically scheduled to encompass the peak spawning period. Two biologists simultaneously count redds for each reach using hand tally-counters. At the end of the reach, each biologist will record the number of redds identified, and counters reset for the next reach. The average of the two observers Chinook salmon redd count from reach is used. The index is defined as the sum of the observed average of the peak counts for each reach between the two flights. Expansions are sometimes made to account for portions of reaches that were not completed due to visibility or mechanical problems.

Escapement Goal Basis: ODFW is currently engaged in analysis which will produce an escapement goal for this stock.

Agency Comments: Coded-wire tagged fall-run Chinook salmon from the Umpqua River indicate that they are harvested in PSC fisheries. Four years of U.S. CTC-funded research has allowed the calibration of redd counts to derive a fish per redd expansion factor so that annual escapements estimates can be made. The average expansion factor from these studies is 3.64 fish per redd. The CV (standard error (SE)/estimate aka percent standard error) of the expansion factor was found to be $29 \%$, which would indicate that the average expansion factor is a reasonably reliable statistic to use for annual estimates of escapement. The escapement estimate for 2010 was 6,184 adults based on redd count expansions. This is more than double the escapement observed in the last five years.

Terminal run estimation is currently being conducted and will require some measure of data mining in order to reconstruct historic terminal catch. Preliminary indications are that the terminal catch of South Fork Umpqua Chinook salmon is insubstantial.

Escapement Methodology: Both MR study based calibration factors and historically conducted surveys have been utilized to measure escapement during the past return year. Normative survey methods are identical to those described in the Siuslaw, Siletz and Nehalem basins. A simple ratio comparison between those years of MR based estimates and observations of peak abundance in normative survey areas have been used to generate a "calibrated" estimate. Values presented in the above graph are based on normative survey estimations, not the calibrated values. Both normative and MR calibrated estimates may be found in the appendix tables.

Escapement Goal Basis: ODFW is currently engaged in analysis which will produce an escapement goal for this stock.

Agency Comments: Methods of estimation based on MR calibrated analysis indicate an adult Chinook salmon escapement for the Coquille basin of 41,104 spawners in 2010. Habitatexpansion based estimates indicate an escapement of 32,318 adult fish. This is the largest escapement observed in this basin since surveys were initiated in 1957. Analysis funded by the CTC is underway that will provide information to designate Coquille Fall Chinook salmon as an
escapement indicator stock for the Mid-Oregon Coast (MOC) Aggregate. Calibrated index of peak counts on standard surveys to relatively precise MR abundance estimates has been selected as an efficient and cost-effective means to measure spawner escapement of Chinook salmon for use in PST fisheries management.

The U.S. CTC advises a CV of $<30 \%$ should be achieved in order for an index to be used as an estimator of abundance within the Chinook salmon management scheme. The CV between the qualifying calibration values computed from studies conducted from 2001 through 2004 for the Coquille River basin is $14 \%$, and the average index value of 0.00874 . This analysis includes eight standard surveys conducted annually on a regular basis. The calibration value is defined as the average peak count per mile of the eight standard surveys divided by the point value of the Petersen estimate. Peak count is defined as the largest sum of live Chinook salmon and carcasses observed on a particular day, per mile over a defined survey reach.

Improvements in applying those calibrated values towards the estimation of this and other Oregon Coastal stocks are currently being discussed within the agency. It is anticipated that historical time series for each of the basins which have MR calibration studies to draw upon (Nehalem, Siletz, Siuslaw, Coquille) will be updated once consensus is reached and finalized by the next reporting cycle.

## 3 SENTINEL STOCKS PROGRAM

### 3.1 Introduction

During recent negotiations within the Pacific Salmon Commission to amend the current Chinook salmon regime under Chapter 3, Annex IV of the Pacific Salmon Treaty, it became apparent that the accuracy and precision of spawning escapement estimates for many important natural stocks of Chinook salmon may not be adequate to support the treaty management process. Reliable estimates of spawning escapements for a large number of natural Chinook salmon stocks over time are critical to assessing and monitoring the status of the resource throughout the treaty area, as well as to determining whether adjustments to particular fisheries are necessary and effective for achieving the long term conservation and production goals of the treaty.

Recognizing the importance of better estimates of Chinook salmon spawning escapements, the Commission conceived the five-year SSP and included it as a specific requirement in the revised Chinook salmon regime (see Paragraph 3(a) of Chapter 3, Annex IV). The SSP is intended to focus on improving spawning escapement estimates for a select subset of important natural Chinook salmon stocks for which existing estimates are critical to fishery management decisions required by the Chinook salmon regime. Improving these estimates will bolster the scientific basis of the Chinook salmon regime, increase confidence in management decisions required under the new regime, and better inform the development of future regimes.

The goal of the SSP is to improve estimates of the spawning escapements for each of the included stocks to a level that meets or exceeds bilateral assessment accuracy and precision standards. Eleven projects were funded in 2010, the second year of the SSP. Summaries for each project are reported in Appendix C.

### 3.1.1 Northern British Columbia

## Skeena River

The return of Chinook salmon to the Skeena River, 93,121 Chinook salmon (CV = 20\%), was estimated from the genetic analysis of representative samples collected at the Tyee test fishery and the spawning abundance in the Kitsumkalum River. The SSP funded the genetic analysis of the test fishery samples in order to identify fish originating from the Kitsumkalum River, which was used to estimate the ratio of fish caught in the test fishery to the spawning grounds for the Kitsumkalum River. The total test fishery catch was expanded by that ratio. In 2010, several additional populations were added to the genetic baseline and the 2009 test fishery samples were rerun. These analysis produce a revised estimated of the 2009 return of Chinook salmon to the Skeena River ( 80,867 fish; CV $=17 \%$ ). Over the migration period of Chinook salmon into the Skeena River, 451 Chinook salmon were radio-tagged, released and tracked to final destination using 11 mobile surveys and 13 fixed station receivers. The overall stock abundance for the radio tagged Chinook assemblage is similar to the abundance derived from the analysis of the Tyee test fishery collections. This study corroborated the basin-wide escapement estimates produced from the genetic analysis of representative samples collected at the Tyee test fishery and the spawning abundance estimated for the Kitsumkalum River.

## Nass River

This SSP project was part of a larger basin-wide escapement program where Chinook salmon were captured and tagged at three fishwheels in the lower Nass River and then recovered and examined for marks at upstream tributaries and two fishwheels at Grease Harbour. The SSP funded the operation of a counting fence on the Kwinageese River, where 2 marked fish were found among the 131 inspected. In 2010, very low numbers of Chinook salmon were caught and marked at the three Gitwinksihlkw fishwheels due to extremely low river discharge during the Chinook salmon migration period. Subsequently, few tags were recovered on the spawning grounds. The MR analysis produced a total spawning escapement estimate of 18,264 Chinook salmon (CV = 25\%).

### 3.1.2 Fraser River

South Thompson River
Spawning escapement to the South Thompson Age 0.3 aggregate was estimated using a combination of genetic, scale age, and CWT information collected from the Northern BC troll fishery and Albion (Fraser River) gillnet test fishery, along with CWT information collected at the Lower Shuswap River. A Bayesian estimation model was used to estimate escapement while considering uncertainty in these information sources. The difference in the spawning escapement estimates based on the Albion (107,000 Chinook salmon; CV $=6 \%$ ) and Northern BC troll fisheries ( 214,000 Chinook salmon; $C V=16 \%$ ) was substantial, and explanation for the difference is currently being investigated; however the prevailing thought is that the Albion test fishery catches may not have been proportional to the size of the South Thompson aggregate over the entire migration period. The spawning escapement to the Middle Shuswap River was $5,038(C V=6 \%)$, as estimated by MR methods. The fish were captured by angling and released with tags and operculum punches, and subsequent carcass surveys were used to recover marked and unmarked fish.

## Chilko River

The spawning escapement, $7,490(\mathrm{CV}=8 \%)$ was estimated using a spatially-stratified MR study design and a Darroch estimator, due to detection of spatial sampling biases. Returning fish were captured by beach seines and angling, and then marked with Peterson tags and operculum punches. Subsequent carcass surveys were used to recover marked and unmarked fish from the spawning grounds.

### 3.1.3 West Coast Vancouver Island

Kaouk River
This MR program relied on troll and tangle net gear to capture returning fish in the estuary, which were marked with radio tags, t-bar anchor tags at the base of the dorsal fin, and operculum punches. Radio tags were detected in the Kaouk River using a receiver near the tidewater boundary and another used during mobile surveys. Fish were captured in the Kaouk River using beach seines and examined for radio tags and other marks, and untagged fish were released with unique marks to prevent double counting and to distinguish them from radio tagged fish. Recovery of six radio tagged fish produced an escapement estimate of 150 fish ( $\mathrm{CV}=27 \%$ ), however at least seven recaptures are required to produce a nearly unbiased escapement estimate (Krebs 1999).

## Burman River

This SSP project estimated spawning escapement (3,543 Chinook salmon; CV = 15\%) using MR methods. Returning fish were captured with beach seines in the lower river and then tagged and released. Carcasses were recovered upstream at the spawning grounds and examined for tags and secondary marks.

## Moyeha River

This study captured and marked live Chinook salmon using beach seines, and then subsequently recaptured them as carcasses. However, a Petersen estimate could not be calculated because no marked carcasses were recovered. A sequential Bayesian method indicated spawning escapement may have been about 690 fish. A lack of tag recoveries prevented evaluation of sampling biases for the tag application and recovery samples.

### 3.1.4 Coastal Washington

## Green River

This study attempted to capture and mark live Chinook salmon using beach seines and then subsequently recapture them as carcasses on all known spawning grounds. However in 2010, high river flow reduced capture efficiencies to zero during the peak and later portion of the Chinook salmon run, which lead to a violation of the equal catchability assumption and too few recaptures. By late September it became clear that the project would not meet its goals, and the carcass recovery survey was modified to support a genetic MR estimate of spawners. The 2010 Green River Chinook salmon escapement estimate will be reported in the next SSP report.

### 3.1.5 Coastal Oregon

Nehalem River
The spawning escapement, 7,097 (CV = 12\%) was estimated using MR methods. Returning fish were captured by using tangle nets and a modified fish ladder, and then marked with operculum punches. Subsequent carcass surveys were used to recover marked and unmarked fish from the spawning grounds. In 2010, the creel survey estimated that 0 tagged fish were harvested by the sport fishery.

## Siletz River

This MR program relied on tangle nets to capture returning fish in the lower river, which were then marked with operculum punches. Carcasses were examined for marks at the spawning grounds. In 2010, the creel survey estimated that 0 tagged fish were harvested by the sport fishery. The preliminary spawning escapement was estimated at 10,985 Chinook salmon (CV = $43 \%$ ). Changes in the habitat at previously successful marking sites and early high water events reduced the numbers of fish marked, and reduced the efficiency of carcass sampling.

Troll, net, sport and total catches include catch of Southeast Alaska hatchery-origin fish and terminal exclusion catch; catches that count towards the all-gear ceiling (with hatchery add-on and terminal exclusion subtracted) are shown in the "treaty catch" column. "-" = not applicable.
${ }^{1}$ The value on top excludes District 108 Stikine catch above base levels. The value below includes it.
${ }^{2}$ Values updated to reflect removal of Andrew Creek Chinook from the terminal exclusion and to include traditional troll Chinook caught in D108 in the terminal exclusion calculation during years with a directed fishery.

${ }^{1}$ Since 1998, the catch accounting year for troll fisheries was set from October 1-September 30. To make comparisons to previous years more meaningful, the same catch accounting period was applied for years prior to 1998.
${ }^{2}$ Troll and net catches from 1996-2004 have been updated with data from the Catch Finalization Project Net catch excludes jacks and small red-fleshed Chinook salmon.
${ }^{3}$ Freshwater catch included with tidal catch.

${ }^{1}$ The historical time series of catches in this year's report has changed from previous year's report. Catches after 1980 have been broken out into non-treaty net and treaty Indian due to the inability to separate commercial versus non-commercial. Catches from 1975-1980 are consistent for sport and total with the later times series.

${ }^{1}$ GW refers to Gitwinksihlkw, the location of the lower fish wheels on the Nass River used to capture Chinook salmon for the mark-recapture estimate.
${ }^{2}$ The Docee River was dropped as an escapement indicator beginning in 2002 due to an inability to obtain reliable escapement estimates.
${ }^{2}$ The Docee River was dropped as an escapement indicator beginning in 2002 due to an inability to obtain reliable escapement estimates.

| Goal | 84,000 |  | 17,857 |  |  |  |  |  | 5,700 |  |  | 4,532 |  | 40,000 |  |

${ }^{1}$ This is the number of naturally spawning adult fish in the Lewis River. The terminal run given is the escapement plus the Lewis River sport catch of wild adults.
${ }^{2}$ The first column gives the estimate based on a mark-recapture project for the entire river. The second column is the estimate based on mark-recapture at Sherars Falls and using the ratio of redd counts above and below the falls.
${ }^{3}$ The 1988 Columbia River Fishery Management Plan included an interim escapement goal of 40,000 natural spawning Upriver Brights at McNary Dam, 38,700 for Hanford Reach and 1,100 Snake River. In 1990, this goal was increased to 45,000 for increased hatchery programs. In 1995, the escapement goal was reduced to 43,500 . In 2002, the escapement goal of 40,000 was agreed to by the Chinook Technical Committee. The 2008-2017 U.S. v Oregon Management Agreement includes a minimum management goal of 60,000 adults for Columbia River and Snake River Upriver Brights combined, including both hatchery and natural production for all areas above McNary Dam. The new agreement also includes 43,500 as the minimum Upriver Bright adult escapement, including Priest Rapids brood stock. The escapements listed are the McNary Dam count, minus Hanford sport and brood stocks. The terminal run is the Columbia River mouth terminal run of Upriver Brights minus the Deschutes River fall Chinook salmon terminal run.

Appendix B.8. Oregon Coastal escapements as estimated via traditional habitat expansion methods and terminal runs of Pacific Salmon Commission Chinook Technical Committee wild Chinook salmon escapement indicator stocks.

## Appendix C. Sentinel Stocks Program in 2010.

The Sentinel Stocks Committee met in Seattle during January, 2010 to review progress for projects funded in 2009 and to develop a list of recommend projects for funding under the SSP in 2010. Thirteen 2010 proposals were considered and 11 were recommended for funding in January of 2010. The Pacific Salmon Commission approved funding for all 11 proposals during the February, 2010 meeting. The proposals were chosen as per the approach outlined in the directive from the Commission to the Sentinel Stocks Committee entitled Implementation Approach for the Chinook Sentinel Stocks Program, October, 2008 and the Sentinel Stocks Program Second Stage Proposal Evaluation, February, 2009. Recommended proposals represent stocks in all five regions specified in the directive (North Oregon Coast, Puget Sound, Fraser River, west coast of Vancouver Island, and NBC). The stocks recommended for study in the SSP are of significant importance to the management of fisheries for Chinook salmon under the Pacific Salmon Treaty. In May 2010, the Sentinel Stocks Committee was informed that the project funded in February of 2010 for the Stillaguamish Chinook stock could not go forward in 2010 due to an unforeseen permitting problem. The SSC held a teleconference and considered a revamped 2010 proposal to implement a MR study of the Kaouk River Chinook salmon stock. On May 20, 2010, the SSC recommended the Kaouk study be implemented in 2010 given the funding made available by the cancelled Stillaguamish study and the Commission agreed to the change. Final funded projects and requested budget amounts for the 2010 SSP are summarized in Appendix Table C-1. Summaries of results from these funded projects are provided in the narratives below.

Appendix Table C.1. Projects and funding levels for the Sentinel Stocks Program in 2010.

| Stock <br> Group | Stock | Title | $2010$ <br> Funding |
| :---: | :---: | :---: | :---: |
| Oregon Coast | Nehalem R. | Nehalem River Chinook Escapement Enumeration | \$279,700 |
| Oregon Coast | Siletz R. | Siletz River Chinook Escapement Enumeration | \$286,900 |
| Puget Sound | Green R. | Abundance Estimate for Green River Chinook | \$128,400 |
| WCVI | Moyeha R. | Moyeha River Chinook Escapement Estimation | \$172,300 |
| WCVI | Kaouk R. | Kaouk River Chinook Escapement Estimation | \$209,100 |
| WCVI | Burman R. | Burman River Chinook Escapement Estimation | \$75,400 |

| NBC | Nass R. | Estimate of Aggregate Population Upper Nass | \$97,900 |

[^5]
## Nehalem and Siletz River Chinook Escapement Enumerations

The Nehalem and Siletz populations of fall Chinook salmon are part of the Northern Oregon Coast (NOC) aggregate. The Nehalem basin is located at the far north of the NOC aggregate, while the Siletz basin is located approximately midway within the NOC aggregate of stocks. The NOC stock aggregate is considered important to both AABM and ISBM fisheries. The NOC aggregate has historically been a very productive, resilient stock complex; however recent failures to reach escapement goals in all three indicator stocks within the aggregate prompted greater interest in quantifying the performance of this group. The prior ten-year average (1990 to 2010) of adult spawning escapement in the Siletz River was 5,839 individuals and in the Nehalem River, the average for the same time period was 7,639 individuals.

ODFW estimated spawning escapement using standard MR methods. Adult fish were captured upon return to each basin using tangle nets in both basins and also a modified fish ladder on the Nehalem River. Fish were marked using operculum punches, the location of which was varied to represent different time frames of freshwater entry. The second capture event(s) occurred on the spawning grounds. ODFW staff surveyed select reaches by foot or by boat and live fish, carcasses, and redds were counted. Carcasses were examined for marks and staff collected biological data from carcasses when possible (length, sex, scales, and other marks). ODFW staff evaluated the likelihood that any MR assumptions were violated using chi-square analyses and Salmonid Population Analysis Software (SPAS). Then, depending on the results of these tests and the data collected, the appropriate estimation techniques were applied. ODFW staff estimated population size from MR data in the Siletz basin using the Chapman version of the Peterson equation. ODFW staff used a stratified estimator (Darroch maximum likelihood, SPAS software) to derive a total estimate for the Nehalem basin. ODFW staff, in part, chose the stratified estimator for the Nehalem because of interest in knowing the relative contribution of the early and late run fall Chinook in the basin. Strata were chosen to represent those runs in terms of timing of freshwater entrance and spawning location. ODFW staff conducted creel surveys in both the Siletz and Nehalem basins. The intent of the creel was to both identify instances when marked fish were removed from the system and to generate a timely and robust estimate of terminal harvest.

Historically, ODFW estimated spawner escapement in Oregon coastal basins using habitatexpansion methodology. Agency and partner employees conducted standard spawning ground surveys to record live and dead counts of Chinook salmon. Then, the largest daily sum of live and dead counts for a given survey location (the peak count) was identified, and an index calculated (number of fish per mile). The index was expanded by the total estimated available
spawning habitat in each basin (in miles). Additional functions are used to adjust for observation and non-random bias. Agency personnel have calculated estimates using these traditional methods while concurrently conducting MR experiments in the Siletz basin since 2005 and in the Nehalem basin from 2000 to 2003 and in 2009 and 2010 (Appendix Table C2 1).

A total of 93 wild adult Chinook salmon in the Siletz River basin were marked during the 2010 return year. A total of 934 adult carcasses were recovered on the spawning grounds; seven of which were marked ( $\sim 7 \%$ recovery rate). The Chapman version of the Petersen estimator was used to develop an estimate of 10,985 Chinook salmon. Using a bootstrap method to derive an estimate with CIs, an estimate of 12,126 Chinook salmon was derived with a Standard error $(\mathrm{SE})=5,226$ and a CV $=43.1 \%$. This CV does not meet CTC standards; an inadequate number of fish were marked to develop a robust estimate. One reason for poor first event sampling success may be that the habitat had changed at a previously successful sampling site. This change made the site less conducive to ODFW typical sampling techniques. Also, some early high water events made marking fish less efficient and carcass sampling hazardous.

Appendix Table C.2. Comparisons of Chinook salmon escapement estimates between traditional, habitat expansion methods and mark-recapture (MR) techniques with associated coefficient of variation (CV).

| Run year | Traditional <br> estimate | Index <br> (fish/mile) | MR estimate | CV of MR <br> estimate |
| :---: | :---: | :---: | :---: | :---: |
| Siletz River |  |  |  |  |
| 2005 | 6,426 | 53 | 11,592 | $47 \%$ |
| $2006^{1}$ | 4,108 | 49 | 14,953 | $16 \%$ |
| 2007 | 528 | 5 | 2,625 | $16 \%$ |
| 2008 | 1,203 | 10 | 1,202 | $20 \%$ |
| 2009 | 2,905 | 24 | 2,213 | $13 \%$ |
| 2010 | 4,225 | 35 | 10,985 | $43 \%$ |
| Nehalem |  |  |  |  |
| River |  |  |  |  |
| 2000 | 6,855 | 51 | 10,678 | $26 \%$ |
| 2001 | 11,662 | 85 | 12,431 | $12 \%$ |
| 2002 | 18,089 | 98 | 19,956 | $5 \%$ |
| 2003 | 10,906 | 77 | 24,196 | $22 \%$ |
| 2009 | 4,070 | 27 | 5,786 | $18 \%$ |
| 2010 | 5,384 | 27 | 7,097 | $12 \%$ |

${ }^{1}$ The 2006 Siletz River mark-recapture estimate is a stratified Darroch estimate; additional analyses are required to assess the influence of potential biases on the accuracy of this estimate.

A total of 254 wild adult Chinook salmon were marked in the Nehalem River basin in 2010. A total of 1,001 qualifying carcasses on the spawning grounds were sampled during the second event. The second event effort included the recovery of 35 marked fish representing a $14 \%$ recovery rate. The Chapman version of the Petersen estimator for the Nehalem River basin in 2010 was 7,097 adult fish. An estimate of 7,250 adult fish was developed using the Darroch maximum likelihood approach; this estimate has a $\mathrm{SE}=1,120$ and a $\mathrm{CV}=15 \%$, meeting the CTC data standard.

Given future and current constraints around personnel and funding resources, this research has focused on identifying a spawning ground survey protocol using peak counts as the index to track fall Chinook salmon spawner abundance. Previous studies in the Siuslaw and Salmon Rivers correlating various survey indices to a MR derived escapement estimate, suggest that
peak counts are the most consistent indicator of abundance when compared to other visual indices. Preliminary analysis of the potential standard surveys located on the main-stem Nehalem and the Siletz River basins have been conducted. Values presented as "calibration value" represent the peak count divided by the MR estimate. The ideal conversion factor would have an inter-annual $\mathrm{CV}=0$ if it tracks perfectly with changes in spawner abundance (Appendix Table C-3). Variability in the inter-annual CV is likely underestimated as this descriptive statistic does not incorporate the precision of the population estimate used, nor does it incorporate the variability within the survey index. Results from standard survey calibration efforts in the Nehalem River basin suggest a relatively strong relationship (CV < 30\%) while the relationship in the Siletz River basin is not as strong; (CV between 46 and $68 \%$ ). ODFW staff hypothesize that one reason for this poor relationship is that the standard surveys in the Siletz and part of the Nehalem represent smaller, tributary type habitat which is not typically productive Chinook habitat. In basins where the relationship between the standard surveys and the MR estimate is strong (i.e. Siuslaw and Salmon Rivers), the standard surveys occur in habitats more typical of Chinook spawning habitat. Therefore, with funding support through SSP, ODFW continues to explore a survey design and estimation method that uses both main-stem and larger tributary reaches outside the historical standard survey design. Preliminary results from these "Select" survey reaches are promising (Appendix Table C-4). Bias detected in some of the MR estimates may exclude these abundance estimates from the calibration analysis, thus additional studies may be necessary to improve confidence in the abundance-index relationship.

Appendix Table C.3. Calibration of adult (>600mm) Chinook salmon encountered on standard surveys to mark-recapture (MR) estimates in the Siletz and Nehalem River basins. Coefficient of variation (CV) values represent the variation around the annual calibration values beginning at the third consecutive year of M/R estimation.

The ODFW intends to identify a cost effective spawning ground survey design in which one or more of the measured metrics accurately and precisely represent Chinook spawner abundance for the basin within the data standards developed by the CTC. The current focus is to increase the proportion of main-stem type habitat surveyed. ODFW has confidence that they can identify survey reaches in which fish counts will more consistently track the spawner estimate derived through the MR component of this study, regardless of run strength or water levels. The intent is to survey select main-stem or large tributary reaches annually
throughout the duration of the studies. This analysis will require multiple years of statistically sound MR experiments before a complete assessment of survey results can be performed with acceptable levels of certainty. ODFW is also exploring a weighted least squares regression approach to determine the relationship between a visual index and the MR estimates of abundance. This technique may allow researchers to include study years where the abundance estimates did not meet the precision standards necessary for the calibration approach. Using this approach, annual spawner escapement could be estimated from the regression equation and confidence bounds derived using peak count data.

Appendix Table C.4. Calibration of adult (>600 mm) Chinook salmon encountered on three select surveys to mark-recapture (MR) estimates in the Siletz River basin. The coefficient of variation (CV) represents the variation around the annual calibration values beginning at year three.

| Run <br> year | Peak <br> count/mile | MR estimate | Calib. <br> value | Calib. <br> CV |

${ }^{1}$ The 2006 Siletz River mark-recapture estimate is a stratified Darroch estimate; additional analyses are required to assess the influence of potential biases on the accuracy of this estimate.

## Abundance Estimate for Green River Chinook

Seven Chinook stocks in Puget Sound are used as escapement indicator stocks by the CTC. The U.S. CTC determined that escapement estimates in Puget Sound fail to meet U.S. CTC data standards. Shortcomings relative to data standards include the lack of usable age, sex, and length data from surveyed streams, the use of unverified expansion factors primarily for redd surveys, and the absence of variance estimates.

The average Green River Chinook salmon escapement from 2000 to 2009 based on redd counts is estimated to be 10,387 fish. The spawning abundance of Chinook salmon in the Green River system, has historically been estimated from redd counts in conjunction with four key assumptions: (1) for area-under-the-curve estimates in mainstem areas, an individual redd is assumed to be visible for 21 days (or occasionally a basin-specific estimate generated through redd life monitoring has been used); (2) for marked-redd censuses in tributaries, all redds are assumed visible and remain marked, and false redds are assumed to either remain unmarked or are marked at a known, consistent rate; (3) each spawning female is assumed to construct only one redd; and (4) 2.5 spawning Chinook are assumed to be associated with each redd ( 1.5 males/female). The Chinook escapement to the Green River has historically been estimated as the sum of five components: (1) Raft Index Area (RM 41.5-43.0) within which a count of all unique redds is made; (2) Raft Supplemental Area (RM 35.0-41.5) within which the redd counts are estimated by multiplying the redd count in the Raft Index Area by the ratio of peak visible redds in the Raft Supplemental Area over the peak visible redds in the Raft Index Area; (3) Newaukum Creek, which uses a method similar to the Raft Supplemental Area method; (4) Aerial Survey Area (RM 29.6-47.0 and RM 56.0-61.0,
excluding raft areas) within which an aerial correction factor is computed as the average ratio of the peak number of redds in the raft areas as counted in the aerial surveys and in the raft surveys (then the number of redds are estimated by multiplying the aerial correction factor and the peak aerial count of redds by the ratio of the unique redds over peak visible redds in the Raft Index Area; and (5) Soos Creek within which the escapement downstream from the hatchery rack is estimated as the sum of all carcasses, plus any live fish counted on the last survey and any fish passed above the hatchery rack.

The project goals for the 2010 study were to: (1) provide an unbiased estimate, via MR, of the number of adult Chinook salmon ( $\geq$ age 3) passing upstream of $\sim R M 26$ in the Green/Duwamish River that spawned naturally, such that the estimate is within $\pm 30 \%$ of the true value $95 \%$ of the time; (2) provide an unbiased estimate of the age 2 "jack" male population, such that the estimate is within $+50 \%$ of the true value $90 \%$ of the time; and (3) develop potential predictive estimators of abundance for future application (beyond the SSP research period), by calculating ratios of MR estimates of abundance to various redd and fish counts or area-under-the-curve estimates. In 2010, the Green River project was not successful in achieving its goals due to higher than normal flow, which occurred from late September through October. These flows reduced capture efficiencies for adult Chinook salmon to zero during the peak and later portion of the Chinook salmon run. This led to a violation of the equal catchability assumption and too few recaptures, which caused this project not to meet its goals.

It became apparent to the Washington Department of Fish and Wildlife that it was unlikely the Green River project would meet project goals by late September, and action was taken to modify the carcass recovery to support a genetic MR estimate of spawners. This methodology was developed in 2010 and was used with success on the Coweeman stock in a study funded through the U.S. Letter of Agreement. During the 2010 recovery event, a genetic sample was obtained from Green River Chinook salmon carcasses. This sample when analyzed along with genetic samples collected during the 2011 juvenile outmigration will allow WDFW to develop an estimate for 2010 spawners by coupling MR estimators and genetic parentage methods. The 2010 Green River Chinook salmon escapement estimate will be reported in the next SSP report.

## Moyeha River Chinook Escapement Estimation

Moyeha River Chinook salmon contribute to the SEAK, NBC, and WCVI AABM fisheries managed under the Pacific Salmon Treaty. The Moyeha River is located in Strathcona Park, Clayoquot Sound, on the west coast of Vancouver Island. The Moyeha River was chosen as a candidate for the SSP for the following four reasons. Habitat in the Moyeha River watershed is pristine and untouched by development. The population has never been purposely enhanced by hatchery supplementation. The stock contributes to the PSC eleven-stream WCVI Chinook salmon escapement index. Moyeha Chinook belong to the South West Vancouver Island Chinook CU, while the Burman and Kaouk populations belong the Nootka-Kyuquot CU. Prior to the SSP, area-under-the-curve index surveys from 2000 to 2009 indicated that escapement averaged 130 Chinook salmon. The objectives of the project were to: (1) estimate total escapement of age-3 and older Chinook salmon; (2) estimate the
proportions of age-3 and older Chinook salmon by age, sex, size and origin; and (3) compare this result to the normative $\mathrm{AUC}_{\text {index }}$ developed annually using snorkel survey methods.

The intended estimate of escapement in 2010 was to be based upon a two event MR experiment focused on age-3 and older Chinook salmon. During the first event, a seine net was deployed using a boat in the Moyeha River approximately 1.75 km and 2.00 km upriver within staging pools. Captured Chinook were tagged in both opercula with numbered Kurllock tags and biological samples were obtained. Chinook were visually identified by gender and post-orbital hypural ( POH ) lengths were measured to the nearest 5 mm . Scales were obtained for ageing. A mutilation mark was applied in the right or left operculum depending on when the salmon was tagged. Tissue samples were preserved to contribute to the coastwide GSI database. Chinook recovered live by beach seine that had been previously tagged were recorded along with any other species captured. A total of 27 individual Chinook were caught during the first event; 3 Chinook were caught twice. Carcass surveys were conducted over the entire anadromous reach from river km 13.5 to the river mouth. Recovered carcasses were sampled for biological data; otoliths were collected for origin determination. A total of 14 carcasses were recovered; none were fish marked during the first event. A total of 12 carcasses had otoliths removed; one otolith sample was destroyed in the lab during processing. The gender of each Chinook carcass was identified; POH lengths to the nearest 5 mm were recorded. Egg retention in females was estimated to assess handling stress.

A Peterson estimate could not be calculated because no marked carcasses were recovered. Instead, an estimate was developed using a sequential Bayesian method from data obtained from the marking event, carcass survey, and re-sight information from the tagged Chinook observed in CDFO swim surveys. The assumption of a closed population was made, although not verified. The Bayesian analysis estimate using exclusively adult data (removing jacks) produced a modal population estimate located at 684-692 Chinook salmon (95\% highest probability density) and there was a $95 \%$ probability that the escapement was at least 440 individuals. Although the data were sparse, this represents a direct probability statement of population size. The potential for introduction of bias through failure to assess tag loss (no marked carcasses were recovered) was addressed by simulation of tag loss rates. In the most extreme case assessed, assuming the loss of $29 \%$ of tags, less than a $3 \%$ reduction in population resulted. It is reasonable to conclude that bias from unequal capture probabilities through mark loss was not a substantive source of error in the estimate of escapement.

The ratio of males to females sampled was 1.88:1.00 during the seining event and 2.50:1.00 for the carcass recoveries with a pooled ratio of 2.08:1.00. The age structure proportions were 0.313 ( $\mathrm{SE}=0.083$, $\mathrm{CI}=0.165$ to 0.524 ) age- $3,0.219$ ( $\mathrm{SE}=0.74, \mathrm{CI}=0.101$ to 0.435 ) age-4, and 0.469 ( $\mathrm{SE}=0.090, \mathrm{CI}=0.291$ to 0.656 ) age-5. Origin proportions determined from otolith examination ( $\mathrm{n}=11$ ) were $0.455(\mathrm{SE}=0.157, \mathrm{CI}=0.170$ to 0.777 ) naturally spawned salmon and 0.545 ( $\mathrm{SE}=0.157$, $\mathrm{CI}=0.231$ to 0.823 ) hatchery strays from the Conuma Hatchery. The hatchery strays were predominantly 3-year old males. Lengths were similar between Chinook caught during the seining event and obtained in the carcass surveys ( $D,=0.182, P=0.985$ ).

The normative area-under-the curve index from the snorkel surveys provided by CDFO was 185 large Chinook with a peak observation of 162 individuals. We were not able to develop an expansion factor for a Peterson estimate, but the expansion factor between the snorkel based normative estimate and the Bayes 0.95 probability minimum estimate was 2.38 .

Considerably more effort is required to mark sufficient fish to generate a reliable estimate of escapement using the Petersen method in the future. An increase in marking effort employing additional capture methods and increased carcass recovery effort is required to achieve the CTC data standard of a CV of $<15 \%$. Larger origin and age sample sizes are required to estimate proportions more precisely.

## Kaouk River Chinook Escapement Estimation

A study of the Kaouk River Chinook salmon stock was conducted in 2010 to estimate the escapement of age 3 and older fish and to estimate the sex, age and length structure of the run. The Kaouk River, located on the west coast of Vancouver Island, British Columbia, is one of three of the six indicator streams for the area identified in the Pacific Salmon Treaty that has never received direct hatchery enhancement. Assessments derived from the normative area-under-the-curve index program on the Kaouk River have estimated escapements that range from 110 Chinook in 2000 to 820 Chinook in 1998 with the ten-year (2001-2010) average estimated at 350 Chinook salmon.

A MR study (Petersen model) was conducted to develop a 2010 escapement estimate. An alternative estimate was also examined using maximum likelihood procedures. Three marks, including a radio tag, were applied to fish in the estuary using troll and tangle net gear. Fish that entered the lower river at the survey boundary were counted as marks (M) by one of two fixed telemetry receivers. Live captures (C) and recaptures (R) occurred in the river using a large beach seine after fish had migrated upstream from the estuary; telemetry surveys were conducted to test for population closure and to examine tag loss and nose-in rates. Carcass surveys were conducted to recover marked and unmarked fish. Biological data and encounter histories of all live and dead marked and unmarked fish were collected.

Twenty-two of the Chinook marked in the estuary entered the Kaouk River ( $\mathrm{M}=22$ ). A total of 45 Chinook were captured by beach seine in the Kaouk River ( $\mathrm{C}=45$ ) including six with radio tags ( $\mathrm{R}=6$ ). The total escapement for 2010 using the Petersen model was 150 Chinook salmon (95\% CI: 74-369; CV=27.3\%). Alternative estimates of 111 Chinook (95\% CI: 71212; CV=30\%) and 114 Chinook ( $95 \%$ CI: 72-218; CV=30\%) were derived using maximum likelihood procedures. The CTC standard of CV $\leq 15 \%$ was not met. The precision standards for age and length structures (i.e. estimated values within $10 \%$ points of the true value $95 \%$ of the time) were not met for age but were met for length. Population closure was likely not met due to the influence of a large storm event on September 25, 2010, and high river discharge through much of October.

A MR approach to estimating escapement had not previously been attempted in this river system. One of the goals of this approach is to eventually use the results of the Petersen estimate to improve the normative area-under-the-curve index program, used to derive an
annual escapement estimate for the Kaouk River. Further, by incorporating robust approaches to the sampling design of future MR surveys, alternative maximum likelihood methods can be paired with existing protocols to produce additional estimates. The replication of studies that accommodate the use of multiple models will in turn lead to the creation of correction and calibration factors, which will provide greater accuracy and precision in future escapement estimates.

## Burman River Chinook Escapement Estimation

The WCVI fall Chinook stock aggregate is an important production group contributing to catches of Chinook in Alaskan and Canadian AAABM and ISBM fisheries. The stock group includes four CUs, described under the Canadian Wild Salmon Policy, occupying the west coast of Vancouver Island. Burman River Chinook belong to the Nootka-Kyuquot CU. The Burman River Chinook population is an escapement indicator described in Attachments I-IV to the Chinook Chapter of Pacific Salmon Treaty. Estimated escapements to the Burman River are summed along with the estimated escapements to five other streams to produce a six-stream index representing WCVI escapement trends. The Burman escapement estimate is also included in a second larger index that includes eight additional WCVI streams.
Exploitation of the aggregate is assumed to be represented by the Robertson Creek Hatchery CWT exploitation rate indicator stock. Low stock status of the WCVI stock group has prompted fishing restrictions in Canadian fisheries since 1995. Over the last 11 years (20002010) escapements to the Burman River averaged 967 adult Chinook. Conservation concerns for the WCVI stock group and other southern stocks prompted a $15 \%$ reduction in the Chinook catch levels in SEAK fisheries in the 2009 Pacific Salmon Treaty. The catch reductions are to be reviewed in 2014 (Paragraph 6 (c)). In the interim, Canada and the U.S. agreed to implement a SSP for five years to improve the precision and accuracy of Chinook escapement estimates, including those in the WCVI area.

The objectives of this study were to: (1) estimate the escapement of age-3 and older Chinook salmon returning to the Burman River to the CTC data standard (CV of $\leq 15 \%$, on average) using a two-event Petersen MR experiment; (2) estimate the proportions of the escapement by age, sex, size and origin (hatchery and wild) with a $95 \%$ probability of detecting a $5 \%$ change in the largest component between years; and, (3) compare MR and snorkel based AUC index estimates of escapement.

Chinook escapement was estimated with a 2-event MR experiment aimed at age-3 and older Chinook. Chinook salmon were captured and marked using a beach seine in the lower river staging area and marks were recovered during systematic carcass surveys over the entire spawning area. Biological samples and marks were also recovered from two hatchery brood collections. All Chinook captured, with the exception of fish released unmarked during the hatchery brood collections, were marked with two individually numbered \#3 Kurl-lock tags attached to the opercula and a secondary mutilation mark. Fish were identified by gender, and post-orbital hypural length was measured. Scales were collected for ageing and otoliths were recovered from carcasses and hatchery brood collections to determine origin.

Between September 7 and October 18, 2010, a total of 733 adult Chinook salmon (165 females and 568 males) were marked in the lower river staging area and remained at large after marked fish removals in hatchery brood collections were deducted. A total of 168 carcasses were sampled of which 34 were marked during the first event of the experiment. The hatchery program removed 187 adult Chinook that are not included in the Petersen estimate. The Petersen estimate of age-3 and older Chinook was 3,543 fish (SE = 513, CV = $14.5 \%)$. The estimate met the program precision standard because of the planned $50 \%$ increase in marking and recovery efforts combined with a larger escapement in 2010. Adding the brood removed yields an estimate of 3,740 adults ( $\mathrm{SE}=513$, $\mathrm{CV}=14.5 \%$ ). The bootstrap mean was $3,491(\mathrm{SE}=5,596)$ suggesting a $1.4 \%$ positive statistical bias in the estimate although the re-samples were not normally distributed. Further analysis is required to determine the cause of the bimodal distribution which suggests two populations were present. The $95 \%$ CI taken directly from the bootstrap re-samples was 1,915 to 5,737 . The Petersen estimate from jacks was 421 fish ( $\mathrm{SE}=2,219, \mathrm{CV}=54 \%$ ), but because it is based upon recovery of a single marked carcass is not reliable.

The Petersen estimate was not affected by tag loss as all previously marked fish were recognizable by the secondary mark albeit not as individuals. We assumed the population on the spawning grounds was closed based on past information. All animals encountered were double checked for marks by two observers and carcasses were destroyed after sampling to prevent double counting. Gender and size selectivity were absent indicating an unstratified Petersen estimate was appropriate. Tagged males (0.043) were recovered at a lower rate in the carcass survey than marked females (0.063), but the difference was not significant ( $X^{2}=$ $0.491, d f=1, \alpha=0.05, P=0.483$ ). There were no significant differences between the cumulative length frequency distributions of all fish marked at the lower river site and either the lengths of all carcasses recovered ( $D,=0.200, P=0.975$ ) or marked carcasses ( $D$, = $0.1000, P=1.000$ ).

The ratio of males to females was 3.40:1.00. Ages of adult fish obtained from the brood stock sample were highly different than the ages of newly marked fish ( $\mathrm{X} 2=43.542, d f=1, P=$ $<0.0001$ ) and were not pooled with age samples obtained during marking. Ages obtained from 400 Chinook during sampling in the lower river were used to estimate age composition as they were collected systematically over the course of the project. Age-3 males were the most abundant followed by age-4 fish in 2010. The proportions at age overall were 0.678 (SE $=0.023)$ age-3, $0.24(\mathrm{SE}=0.021)$ age $4,0.075(\mathrm{SE}=0.013)$ age-5, and $0.008(\mathrm{SE}=0.004)$ age-6. Stream-type Chinook were not observed in the 2010 sample. The proportions by age for males were $0.630(\mathrm{SE}=0.024)$ age- $3,0.142(\mathrm{SE}=0.018)$ age-4, $0.033(\mathrm{SE}=0.009)$ age5 and no age-6 fish. The proportions by age for females were 0.048 ( $\mathrm{SE}=0.011$ ) age-3, 0.098 ( $\mathrm{SE}=0.015$ ) age-4, $0.043(\mathrm{SE}=0.010)$ age-5, and $0.008(\mathrm{SE}=0.004)$ age-6. The large proportion of age- 3 males may have caused the bimodal bootstrap distribution.

Origin proportions estimated from thermal otolith marks were $0.055(\mathrm{SE}=0.012)$ naturally spawned and the remainder originated from hatcheries: $0.844(\mathrm{SE}=0.002)$ of the total were from the Burman River hatchery program; and $0.100(\mathrm{SE}=0.016)$ had strayed principally from the Conuma Hatchery. The origin proportions of wild and all hatchery fish in 2010 were not significantly different ( $X^{2}=0.512, d f=1, P=0.474$ ) than that observed in 2009 ( $\mathrm{n}=$
347). The origin proportions of natural, Burman River hatchery, and hatchery strays in 2010 were significantly different ( $X^{2}=66.31, d f=2, P<0.0001$ ) than in 2009 due to fewer hatchery strays and a larger Burman hatchery contribution.

The normal area-under-the curve index snorkel survey estimate for 2010 was 3,028 age-3 and older Chinook, including hatchery brood. Survey life was assumed to average ten days, and observer efficiency was estimated to be $80 \%$. The snorkel based estimate is preliminary and subject to revision. Adding the brood removed downstream to the Petersen estimate yields 3,740 adults $\geq$ age- 3 ( $\mathrm{SE}=513, \mathrm{CV}=14.5$ ). The expansion factor between the snorkel based estimate and the MR estimate was 1.23 in 2010. The long term intent of the Burman River escapement program is to develop an expansion factor for the snorkel based estimates within the data standard. This was the second year of the MR program designed to estimate an expansion factor. At least one more MR experiment will be required to evaluate the precision of the expansion factor. Sampling effort in the river and carcass surveys were increased by $50 \%$ in 2010 over the 2009 effort and appears sufficient to obtain the desired level of precision provided the escapement does not decline.

## Abundance Estimate South Thompson Aggregate

A Bayesian model was developed to estimate the escapement of an aggregate salmon stock based on genetic stock identification data and recoveries of CWTs from a hatchery indicator stock in distant fisheries and on the spawning grounds. This model was applied to data from 2009 for the South Thompson Age 0.3 Chinook Aggregate, a significant component of the Fraser early model stock used by the CTC. The expected escapements for the South Thompson aggregate, based on data from the Fraser River gillnet test fishery (Albion) and NBC troll fishery were $169,000(C V=0.06)$ and $155,000(C V=0.17)$, respectively. In 2010, the analysis was repeated using data from the same two fisheries collected within the same year. The expected escapements based on the 2010 data from the Fraser River gillnet test fishery (Albion) and NBC troll fishery were 107,477 (CV=0.06) and 214,434 (CV = 0.16), respectively. The spawning escapement for the Middle Shuswap River, estimated by MR methods, was 5,038 (CV=0.06) in 2010.

For 2009, the differences in the two estimates were minor and well within variation due to sampling error. Age-specific estimates of escapement were relatively precise in cases where the uncertainty in the expanded number of CWT recoveries in the fisheries was low. For 2010, the differences between the two estimates were pronounced with the Albion test fishery derived estimate being about one-half that produced when using NBC troll fishery data. The explanation for such a large difference between the estimates is currently being investigated; however the prevailing thought is that the Albion test fishery catches may not have been proportional to the size of the South Thompson aggregate over the entire migration period. Investigators are looking at the factors which may have influenced catch rates in the test fishery (e.g. water clarity, or influence of extremely abundant co-migrating sockeye salmon in 2010). Analysis is also continuing on ageing samples collected from Chinook carcasses throughout the South Thompson aggregate with the objective of determining the representativeness of the age-specific escapements estimated using the Lower Shuswap CWT indicator stock.

Unlike 2009, the recovery of an age-5 CWT in the 2010 NBC troll fishery samples allowed for a more reliable estimate of escapement for the age class. Increasing the number of CWT recoveries remains essential to reduce uncertainty in age-specific escapement estimates. Therefore, CWT releases for the Lower Shuswap River indicator continue at a higher level than previous. Beginning in 2010, tagging was increased from 250,000 to 500,000 CWT and adipose clipped fish, and a second year of tagging occurred at the Middle Shuswap River with 150,000 CWT and adipose clipped fish. The releases in 2011 at Lower and Middle Shuswap Rivers continued at the 500,000 and 150,000 levels, respectively.

## Chilko River Chinook Mark-Recapture

The 2010 escapement of summer-run (age 1.3 Stock Group) Chinook salmon to the Chilko River was estimated using a two event MR study, and concurrent aerial visual surveys. Fish behavior and distribution in the terminal area was monitored using radio telemetry. Petersen tags and sex-specific secondary marks were applied to 1,467 adult Chinook salmon captured using a combination of seining and angling. Recovery sampling was undertaken on carcasses, and 583 marked fish were recovered from a total recovery sample of 2,360 adult carcasses. The age composition of the recovery sample was $0.4 \%$ age $3_{2}, 51.9 \%$ age $4_{2}, 43.8 \%$ age $5_{2}$, and $3.9 \%$ age $6_{2}$. All samples showed a two-year freshwater growth pattern. Only fourteen tags were applied to jacks, of which only one was recovered from a total recovery of five jacks; therefore, a valid estimate of the jack escapement could not be calculated.

The results of the bias testing indicated that measurable sources of stress including holding time, marking, number of times recaptured, and release condition did not have a significant impact on the subsequent behaviour of the marked fish. Based on the radio telemetry and aerial survey data, the MR assumption of closure was met; however, telemetry data indicated incomplete mixing, as the majority of males and females spawned and were recovered in the same area that they were marked and released (upper and lower). As there was strong evidence of spatial bias in the application sample for both sexes and in the recovery sample for females, the Stratified Population Analysis System (SPAS) was used to estimate escapements. The results confirmed that due to incomplete mixing between the upper and lower stratum for males and females, there was a requirement to use the maximum likelihood Darroch method. The adult spawning population estimate was 7,490 (CV = 7.6\%) Chinook salmon with sex-specific escapement estimates of 3,678 males ( $C V=9 \%$ ) and 3,812 females ( $\mathrm{CV}=12 \%$ ). The Peak Count estimate of escapement based on the aerial survey data was $6,345,15 \%$ less than the Darroch estimate. The measured peak count expansion factor was 1.82 based on the peak count of 4,124 spawners, holders, and carcasses on September 2, 2010.

Results from the radio telemetry study and analyses of the 2010 Chilko River Chinook salmon MR data will inform modifications to the study design that will minimize the potential for bias in future Chilko River Chinook salmon MR studies.

## Chinook Escapement Estimation to the Skeena Using Genetic Techniques

The Skeena River has the second largest aggregate of Chinook salmon spawning populations in British Columbia and is one of the escapement indicator stocks defined by the PST for NBC/CBC. Chinook salmon escapements to the Skeena River are currently represented by an index that includes approximately 20 populations surveyed annually using a variety of techniques. The Kitsumkalum River is the exploitation rate indicator stock for the Skeena Chinook complex and spawning escapements have been estimated using a MR program since 1984. Other escapement estimates that contribute to the index are based on fish weir counts, visual observations from helicopter, fixed wing aircraft, boats and foot surveys. The index of Chinook salmon escapement to the Skeena aggregate has averaged 50,000 fish since 1984. The Kitsumkalum indicator stock represents approximately $30 \%$ of the spawners in the escapement index. The Bear and Morice River populations have contributed 20 and $26 \%$ of the escapement index, respectively, since 1984. Skeena Chinook salmon are encountered in the AABM fisheries of SEAK and NBC. They also contribute to the ISBM fisheries in NBC including gillnet, tidal sport, non-tidal sport, tidal FN and non-tidal FN fisheries. Skeena Chinook are north migrating so they do not contribute to the WCVI fisheries nor do they contribute appreciably to ISBM fisheries south of the Skeena River.

The number of Chinook salmon returning to the Skeena River in 2009 and 2010 was estimated using the proportion of Kitsumkalum River fish measured from genetic samples collected at the Tyee test fishing site and the estimate of the Kitsumkalum Chinook escapement from an independent MR project. The 2010 return of Chinook salmon to the Skeena River was estimated at 93,121 fish with a standard deviation of 18,688 fish (CV = 20\%) using genetic stock identification techniques. Genetic samples were analyzed from 839 Chinook salmon caught at the Tyee Test Fishery and the proportion of the catch identified as Kitsumkalum Chinook salmon using genetic techniques was $14.7 \%$ with a standard deviation of $2.0 \%$. The escapement of large Chinook salmon to the Kitsumkalum River was estimated at 13,712 fish with a standard deviation of 2,033 fish from an independent MR estimate.

A number of additional populations were added to the genetic baseline from the Skeena River watershed in 2009 and 2010. Existing genetic data from the 2009 Tyee Test fishery were run against the improved baseline to revise the 2009 estimate of Skeena River Chinook escapement to 80,867 fish with a standard deviation of 13,799 fish (CV = 17.1\%).

The 2010 data were compared with revised genetic analyses completed for Chinook salmon samples collected at Tyee in 2000, 2001, 2003 and 2009 (Appendix Table C-5). Preliminary estimates for the Chinook return to the Skeena River had CV's between $15.2 \%$ and $17.2 \%$. Improvements were expected in 2009 and 2010 as the sample collections were increased at Tyee and the genetic baselines were improved. However, these improvements were not realized due to broader variance around the MR estimate of Kitsumkalum River Chinook escapement.

Appendix Table C.5. Skeena Chinook salmon escapement past Tyee from the proportion of Kitsumkalum Chinook identified in the Tyee Test Fishery compared with the index.

| Year | Kalum esc. from MR |  | CV Kalum esc. | N Tyee DNA | Kalum in Tyee DNA (\%) | SD <br> Kalum in Tyee DNA | CV Kalum in Tyee DNA | Total Skeena esc. from DNA | SD <br> Skeena esc. est. | CV <br> Skeena esc. est. | Skeena Esc. Index |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 14,722 | 1,200 | 0.08 | 775 | 15.55\% | 0.020 | 0.13 | 94,668 | 14,401 | 0.15 | 51,804 |
| 2001 | 23,839 | 2,275 | 0.10 | 569 | 19.73\% | 0.026 | 0.13 | 120,803 | 19,410 | 0.16 | 81,504 |
| 2003 | 23,608 | 2,601 | 0.11 | 468 | 22.30\% | 0.029 | 0.13 | 105,857 | 18,162 | 0.17 | 56,758 |
| 2009 | 10,703 | 1,424 | 0.13 | 1,155 | 13.24\% | 0.014 | 0.11 | 80,867 | 13,799 | 0.17 | 38,597 |
| 2010 | 13,712 | 2,033 | 0.15 | 839 | 14.72\% | 0.012 | 0.14 | 93,121 | 18,688 | 0.20 | 43,331 |

SD = Standard Deviation, $\mathrm{N}=$ sample size, $\mathrm{v}=$ variance, $\mathrm{CV}=$ coefficient of variation, esc. = escapement, est. $=$ estimate; Calculations from TCChinook (99)-3 where $v(z)=z^{\wedge} 2\left(\left(v(y) / y^{\wedge} 2\right)+\left(v(x) / x^{\wedge} 2\right)\right)=z^{\wedge} 2\left(c v^{\wedge} 2(y)+c v^{\wedge} 2(x)\right)$ Kalum = Kitsumkalum

An objective for the project was to provide an escapement estimate for Skeena River Chinook salmon with a CV of less than $15 \%$. While the project failed to meet these criteria in 2009 and 2010, the preliminary estimates represent a significant improvement over existing indices since they are estimates of total passage rather than indices and these estimates include estimates of variance. Variance estimates cannot be produced for the escapement indices of Skeena Chinook because of the combination of different escapement techniques involved. Accurate determination of spawning escapements will require estimates of fishery removals upstream of Tyee and stock identification for fisheries between Tyee and the Kitsumkalum River to determine if Kitsumkalum fish suffer different fishing mortalities than other Skeena components.

## Skeena Chinook Radio-Telemetry

The Skeena River is the second largest Chinook salmon producing watershed in British Columbia. It hosts more than 30 populations of Chinook which spawn in over 56 census units. In 2010, we carried out the first watershed-wide radio-telemetry project for Chinook salmon in the Skeena River. Our objectives were to tag Chinook and trace them to their spawning sites, determine the effectiveness of the latest Skeena Chinook microsatellite DNA baseline in identifying stocks, and develop information on Chinook populations in the upper Skeena. Chinook were captured, DNA samples were taken, and tags were applied near the head of the Skeena estuary with supplemental tagging at Kuldo above the Babine River. A total of 451 radio-tags were applied. Chinook locations and migrations were determined by 13 fixed stations along the Skeena and major tributaries and by 11 mobile surveys with a small airplane supplemented with boat and helicopter surveys.

Radio-tag retention was $97 \%$. Mobile surveys located $75 \%$ and $93 \%$ of the Chinook tagged at Kwinitsa and Kuldo, respectively, and $93 \%$ of the Chinook that were tagged at Kwinitsa proceeded upstream of Oliver. Chinook movement up the Skeena River was fairly uniform, and in general, the fish moved steadily upstream at 15 to $25 \mathrm{~km} /$ day. As the various Chinook stocks separated and approached their destination tributaries they appeared to slow down. This was particularly evident below the Kalum River. Chinook that traveled up major tributary rivers spent significantly more time at the river confluences than fish heading
further up the mainstream ( $\mathrm{p}<0.0001$ for the Bulkley, Sustut and Kispiox River confluences). The number of Chinook known to have been taken in fisheries is relatively low. Fourteen percent of the Chinook tagged in the lower river were captured in fisheries above the tagging site. Most of the terminal and in-river fishing for Chinook is by FN (66\% of the total fishing).

The radio-tagged Chinook were analyzed using genetic techniques and assigned to the 32 sub-populations defined in the Skeena Chinook baseline. The genotypes of $99 \%$ of the Chinook that were submitted for analysis were successfully obtained. The overall stock abundance for the radio tagged Chinook assemblage is similar to the abundances derived from analysis of the Tyee Test Fishery collections. Recent improvements to the Skeena Chinook baseline have demonstrated the importance of the upper Skeena Slamgeesh and Squingula stocks which now appear to be among the 10 largest Skeena sub-populations. In the lower river, relatively few tags were tracked to the Kitsumkalum watershed. The tracking data and genetic analyses suggest that the Kitsumkalum run constitutes less than half of the Chinook escapement to the lower Skeena. Most of the microsatellite DNA assignments agreed with the radio-telemetry results. Slightly over half (52\%) of the Chinook returned to the specific sites predicted by the baseline genetics. If we take a less stringent view and divide the Chinook cladogram into the five identified clades, then $77 \%$ of the Chinook returned to predicted spawning localities.

The widespread mobile surveys found Chinook present at all of the known spawning zones as well as being widely distributed downstream of these sites. Of the 382 Chinook that were tagged and traced to an upstream location, $30 \%$ were found outside of known or appropriate seeming spawning areas. As the mobile surveys took place near the end of the spawning season and many tags were relocated in nearby localities weeks apart, it is unlikely that these Chinook spawned. It is apparent that there are considerable losses in transit and furthermore that many Chinook end up at unexpected spawning sites. The genetic evidence and radiotelemetry data can be reconciled if the straying Chinook have low breeding success. The overall success of microsatellite DNA in predicting the clade and stock assignments of tagged fish, however modest, supports the continued use of genetic analysis of representative samples of Skeena Chinook such as from the Tyee Test Fishery to determine escapements of the larger Skeena Chinook components. The migratory delays observed with radio-tagging were much more prominent at the lower Skeena tagging site located at the freshwater end of the estuary than at the upriver site at Kuldo. Nearly $90 \%$ of the tagged fish at the lower station dropped back for some period of time and $16 \%$ never came back upriver. At the upriver tagging site, only $10 \%$ of the fish (12 of 119) dropped back downstream. The more extreme reaction to capture and tagging of Chinook in the estuary is likely related to the osmoregulatory stress of fresh water entry.

## Estimate of Aggregate Population Upper Nass

The Upper Nass River Chinook salmon aggregate forms one of the existing CTC wild Chinook indicator stocks. This is a large stock group that has averaged 22,000 spawners per annum ( 45,000 total run) over the last decade and includes 16 separate populations including the Tseax River and all other populations that spawn within the Nass watershed, upstream of
the confluence of the Nass and the Tseax Rivers. The Upper Nass River Chinook aggregate is important and represents a stable proportion of the Chinook salmon stocks taken in the AABM and ISBM fisheries in northern BC and Alaska. The Upper Nass River Chinook aggregate is a completely natural population with no history of enhancement.

Since 1994, MR estimates of the Upper Nass River Chinook aggregate have been derived by marking adult Chinook salmon ( $\geq 50 \mathrm{~cm}$ nose-fork length) with operculum tags at fish wheels operated on the mainstem Nass River near the Nisga'a community of Gitwinksihlkw. Live Chinook salmon are subsequently examined for marks at the Meziadin fishway and Chinook salmon carcasses are examined for marks at other Upper Nass River tributary locations. Carcass recovery locations have varied over the years but have been predominantly from Damdochax Creek and the Kwinageese River. Effort has been focused on these two Chinook salmon stocks as they were found to significantly contribute to the Upper Nass River Chinook aggregate population ( $\sim 30 \%$ ) based on stock composition results from radiotelemetry studies conducted in 1992 and 1993. From 1994 to 2008, Upper Nass River Chinook aggregate MR estimates have achieved coefficients of variation (CV) less than or equal to $15 \%$ in 9 of 15 (60\%) years. The main factor determining the CV has been the number of marked adult Chinook salmon examined and recovered at terminal spawning areas in the Upper Nass River watershed. Recoveries of marked Chinook salmon at the Meziadin fishway alone have not been sufficient to generate precise MR estimates for the Upper Nass River Chinook aggregate; hence, additional recovery efforts on other tributaries are required each year to achieve a CV of $15 \%$ or less.

In 2009, the PSC funded an Upper Nass River Chinook aggregate MR program as part of the SSP where 1,213 adult Chinook were marked and 1,692 fish were examined with 57 marked recoveries to generate an Upper Nass River Chinook aggregate abundance estimate above Grease Harbour of 26,864 adults ( $\mathrm{SE}=5,106$; $\mathrm{CV}=13.1 \%$ ). The MR study was designed to meet or exceed the data standard of generating an unbiased escapement estimate with a CV of $15 \%$ or less and to identify repeatable procedures for future studies. The additional funding received from the PSC in 2009 helped achieve the data standard for the Upper Nass River Chinook aggregate MR estimate by permitting sufficient tag recovery efforts. Two key recommendations were made from the 2009: (1) to operate a third fish wheel at Gitwinksihlkw to increase mark rates of all size groups for assessing any potential size selective biases associated with the aggregate MR estimates, and (2) to continue mark recovery operations at Meziadin Fishway, the Kwinageese weir and Damdochax Creek.

In 2010, the PSC funded Year 2 of the Upper Nass River Chinook aggregate MR program. Adult Chinook salmon were captured with three fishwheels (FW1, FW2, and FW7) operated on the lower Nass River near the community of Gitwinksihlkw from 1 June to 22 September and uniquely marked with numbered aluminum "chick-wing" tags applied to the left operculum. Of the 363 adult Chinook salmon marked at the Gitwinksihlkw fishwheels from 3 June to 6 September, 112 were censored to account for tagging related mortality and estimated in-river fishery removals between Gitwinksihlkw and Grease Harbour, leaving 251 marked fish available for recovery upstream of Grease Harbour. A total of 1,184 fish were examined for marks at upstream tributaries of which 15 were marked. Marking was influenced by extreme low water levels at Gitwinksihlkw that resulted in below average
catches of adult Chinook and marks applied for recovery. Due to the small number of marked recoveries, testing for unequal probabilities of capture in either sampling event (by size, sex, age, or temporal/ spatial strata) proved difficult. However, genetic (stock and sex identification) analyses was conducted on marked fish that enabled a review of stocks that were tagged, harvested and recovered by size and sex in 2010. Using a pooled Petersen estimator, the estimated abundance of adult Chinook salmon above Grease Harbour in 2010 was 18,656 ( $\mathrm{SE}=4,494$; $\mathrm{CV}=25 \%$ ). Subtracting the in-river harvests above Grease Harbour (392) yielded a net escapement (spawners) estimate of 18,264 adult Chinook salmon returning to the Upper Nass River in 2010 (95\% C.I.: 11,980 to 29,222). Adding the catch $(2,419)$ from all fisheries above the Gitwinksihlkw fishwheels to the net escapement estimate yielded an estimate of the total return of adult Chinook salmon to the Gitwinksihlkw fishwheels in 2010 of 20,683 (95\% C.I.: 14,399 to 31,641).

A total of 462 Chinook salmon were successfully aged at the Gitwinksihlkw fishwheels in 2010 of which $31.2 \%$ were age $5_{2}$, $30.3 \%$ were age $3_{2}, 26.0 \%$ were $4_{2}$, and $7.8 \%$ were age $6_{2}$. The remainder of the fish were age $2_{1}(0.2 \%)$, age $3_{1}$ (1.1\%), age $4_{1}(0.4 \%)$, age $4_{3}(1.3 \%)$, age $5_{3}(1.1 \%)$, age $6_{3}$ ( $0.4 \%$ ), and age $7_{2}$ ( $0.2 \%$ ).

The 2010 MR estimate did not meet the data standard (i.e., $\mathrm{CV} \leq 15 \%$ ) due to very low numbers of adult Chinook caught and marked at the Gitwinksihlkw fishwheels and subsequently recovered on the spawning grounds. Based on the results from Year 2 of this study, it is recommended that a third fishwheel (FW7) continue to be operated at Gitwinksihlkw in order to increase the sample size of marked fish. It is also recommended that adult Chinook salmon be marked at the upper Grease Harbour fishwheels if an interim target of 415 marks has not been met at the Gitwinksihlkw fishwheels by 23 June due to low water or other catchability conditions in order to reach a final target of greater than 1,000 marks on the aggregate population. Finally, mark-recovery efforts are recommended to continue at the Meziadin fishway, Kwinageese weir, and in Damdochax Creek. The provision of $\$ 97,900$ from the PSC in 2010 was sufficient to support the operation of a third fishwheel at Gitwinksihlkw for additional marking and for sufficient mark-recovery efforts at Kwinageese, Damdochax and other systems. However, to ensure the CTC data standard can be achieved on an annual basis under all environmental conditions, an increase in funding in future years ( $\sim 7 \%$ ) would be needed to support additional tagging efforts at the Grease Harbour fishwheels when marks applied at Gitwinksihlkw are low and below target.
