# Preface <br> The Pacific Salmon Treaty Chinook Rebuilding Program 

The Pacific Salmon Treaty includes a commitment to:
"halt the decline in spawning escapements of depressed stocks; and attain by 1998, escapement goals established in order to restore production of naturally spawning chinook stocks, as represented by indicator stocks identified by the Parties, based on a rebuilding program begun in 1984."

The goal of the program is to rebuild depressed naturally-spawning stocks and restore production through progressive increases in spawning escapements achieved through a combination of catch ceilings in selected mixed-stock fisheries and harvest rate limitations in nonceiling, passthrough fisheries. The Pacific Salmon Commission instructed the Chinook Technical Committee to "develop procedures to evaluate progress in the rebuilding of naturally spawning chinook stocks." The February 1987 Chinook Technical Committee Report, "Assessing Progress Toward Rebuilding Depressed Chinook Stocks," established an evaluation framework that documented an indicator stock program, identified information requirements, and recommended analytical procedures for the assessment of rebuilding. The Committee also identified a number of policy issues that had to be resolved before final conclusions could be reached regarding the status of rebuilding on a regional or coastwide basis. Agreement on those issues has not yet been reached.

In assessing the status of individual stocks under the rebuilding program, the Committee identified three main elements that must be examined: 1) spawning escapement levels; 2) fishery harvest and stock-specific exploitation rates; and 3) production responses to increases in spawning escapements.

Due to time constraints, the CTC had to reduce the scope of this year's report. The report provides an evaluation using data through 1994, and includes recent catch in fisheries of concern to the Pacific Salmon Commission (Chapter 1), assessment of spawning escapements for 44 escapement indicator stocks (Chapter 2), and fishery-harvest and stock-specific-exploitation rates based on 35 exploitation rate indicator stocks (Chapter 3).

## EXECUTIVE SUMMARY

This report contains a partial assessment of the chinook rebuilding program through 1994. As directed by PSC Commissioners, the CTC was to complete the first three chapters of the Annual Report summarizing catch, escapements, and exploitation rates through 1994.

## Key Points in the 1994 Annual Report

## 1. 1994 Chinook Catch (Chapter 1)

In 1994, the PSC did not agree on catch ceilings. Therefore, the CTC compared catches in each fishery with 1985 base-level ceilings. For all PSC ceiling fisheries in 1994, catches were below the base-level ceilings and substantially lower in the WCVI troll and Strait of Georgia troll and sport fisheries (Table 1-1, pg. 1). Cumulative deviations could not be calculated for 1993 and 1994, since PSC ceilings were not agreed on and some agencies set catch targets below the base ceiling levels due to reductions in chinook abundance or U.S. Endangered Species Act restrictions. Instead, cumulative deviations were calculated for 1987 through 1992 only (Table 13 , pg. 3).

## 2. Escapement Assessment (Chapter 2)

This year's assessment of escapement trends included 44 naturally spawning escapement indicator stocks and the procedures used in last year's report (TCCHINOOK (94)-1). For the 36 stocks with escapement goals, 14 (39\%) were assessed as Above Goal or Rebuilding and 22 (61\%) were classified as Indeterminate or Not Rebuilding. Declines in escapement have not been halted for 8 of the 22 stocks classified as Indeterminate or Not Rebuilding. For the 36 stocks with escapement goals, the assessment shows an increasing proportion of stocks classified as Not Rebuilding since 1988 and a general decline in the proportion of stocks classified as Above Goal and Rebuilding since 1989 (see Figure 2-2, pg. 31). For the 8 stocks without escapement goals, declines in escapement have been halted for 7 and for 1 it could not be determined whether or not the decline had been halted.

The CTC recognizes limitations to assessing rebuilding based solely on escapement values and trends. Due to these concerns, some CTC members proposed an additional rebuilding assessment criterion based on the proportion of the maximum surplus production expected from recent escapements for each escapement indicator stock. The CTC agrees with the development and evaluation of production criteria to determine if one should be incorporated in future rebuilding assessments, but could not, at this time, evaluate the merit of any particular production criterion.

## 3. Exploitation Rate Assessment (Chapter 3)

The CTC conducted an extensive evaluation of alternative estimators of fishery indices. In recent years, concerns have been raised regarding limitations of the current CTC Fishery Index (FI), in particular regarding the inability to incorporate CWT data for stocks lacking base period data and potential difficulty in assessing stock exploitation due to changes in the conduct of fisheries (e.g., changes in seasonal patterns of fishing). The CTC examined time-area stratification of the SEAK troll fishery and different estimators for a fishery index. The CTC recommended the use of a new
stratified estimator in the SEAK troll fishery and the continued use of the CTC FI in other fisheries. The performance of alternative indices in these other fisheries can be evaluated but could not be completed in the time available. Details of the CTC evaluation are included in Chapter 3 and the new Stratified Proportional Fishery Index (SPFI) and the CTC FI values are presented for the SEAK troll fishery in Figure 3-3 (pg. 44).

Examination of coded-wire tag data for 18 of the 35 exploitation rate indicator stocks (identified in Table 3-5, pg. 40) indicated that:
a) In 1994, fishery indices were below base levels in each PSC ceiling fishery (Table 3-6, pg. 48). Fishery indices for 1994 were reduced from base period levels by $24 \%$ in the SEAK troll, $30 \%$ in NCBC troll, and $43 \%$ in WCVI troll. For the Strait of Georgia troll and sport fishery, the 1994 fishery index was $9 \%$ below base period levels and near the 1985-1994 average index value. The 1994 fishery indices for SEAK troll, NCBC troll, and GS troll and sport are higher than the projected indices from the 1984 CTC chinook model. The 1994 fishery indices for WCVI are lower than the 1984 projections (see Figures 3-4 through 3-7, pgs. 49-50).
b) In 1994 nonceiling fisheries, harvest rates were consistent with passthrough (as estimated by applying the nonceiling index described in Chapter 3). The nonceiling index described in this report adjusts for the problem of differential exploitation on hatchery and wild stocks in terminal areas. Nonceiling indices previously reported for the North Puget Sound summer/fall stock group are now reported for each stock. When evaluated in this way, harvest rates for each stock are now consistent with passthrough in 1993 and 1994 (as estimated by applying the nonceiling index).
c) Total mortality and reported catch brood exploitation rates declined in 1994 for all of the stock groups examined except LGS. Changes in brood exploitation rate indices relative to the base period varied widely between the seven stock groups examined. In four groups, exploitation rates based on total fishing mortalities presently indicate no reductions from the base period values (SEAK/TBR-I, WCVI, LGS, NPS-S/F). The three other groups (UGS, SPS-S/F, WACO) indicate about a 30 to $40 \%$ reduction in ocean exploitation rates relative to the base period. For three stocks, there are brood year exploitation rate projections from the 1984 CTC chinook model. The 1994 brood year exploitation rates for WCVI (Figure 3-18) and LGS (Figure 3-20) are higher than the 1984 projections. The 1994 brood year exploitation rates for WACO (Figure 3-23) are lower than the 1984 projections.

## 4. Appendices

Due to the limited scope of this report, stock catch distributions are not discussed in the text, but are only presented in Appendix D. Additional information on escapements, terminal runs, and the methods and data used to calculate the exploitation rate indices can be found in Appendices A, B, C and E.

## Recommendations

Given the limited time available for this assessment and the partial evaluation conducted, the CTC did not discuss recommendations following from this report.

## 1. 1994 CHINOOK CATCH

### 1.1 1994 CHINOOK SALMON CATCHES IN FISHERIES WITH CEILINGS

Estimates of 1994 catches for each fishery supposed to be managed under a harvest ceiling established by the Pacific Salmon Commission (PSC) are presented in Table 1-1. Although there were no PSC ceilings in 1993 or 1994, 1985 "base ceilings" are given for comparison. The catch data are preliminary, but major changes are not expected. Catches in all chinook fisheries of interest to the PSC for the years 1991-1994 are documented in Table 1-2.

Table 1-1. Catches for PSC ceiling fisheries in 1994. There was no PSC agreement on 1994 ceiling levels, so differences from base level ceilings are given for comparison.

| Area (Gear) | Base Cefling | Catcl | Dirference |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Numbers | Percent |
| Southeast Alaska (T,N,S) ${ }^{2}$ | 263 | 232.5 | -30.5 | -11.6\% |
| North/Central B.C. $(\mathrm{T}, \mathrm{N}, \mathrm{S})^{3}$ | 263 | 250.9 | -12.1 | -4.6\% |
| West Coast Vancouver Island (T) | 360 | 145.8 | -214.2 | -59.5\% |
| Strait of Georgia (T,S) ${ }^{4}$ | 275 | 83.8 | -191.2 | -69.5\% |

1 T=Troll; N=Net; S=Sport
2 The actual total catch was 264,300 chinook, including a hatchery add-on of 31,800 .
3 Excludes 7,210 chinook caught in terminal areas.
4 Due to budget constraints, the catch in the Strait of Georgia recreational fishery was only estimated through October in 1994 (based on past averages, this period accounts for at least $95 \%$ of the annual catch).

### 1.2 CUMULATIVE DEVIATIONS FROM CATCH CEILINGS

A 7.5\% cumulative management range was established by the PSC in 1987. In the absence of a PSC agreement for 1994 fisheries, cumulative deviations from ceilings do not include 1994. Annual catches (without add-on) for 1994 and deviations from catch ceilings for 1987-1993 are given in Table 1-3.

Table 1-2. Summary of the 1991-1994 total chinook catches (including terminal area exclusions and hatchery add-ons) in fisheries relevant to the U.S./Canada Pacific Salmon Treaty (numbers in thousands of fish).

Southeast Alaska troll chinook catches shown for Oct. l - Sept. 30 catch counting year.
${ }^{2}$ British Columbia net catches include only adult fish (over 5 lb . round weight). Native food fishery catches are not included. North/Central Coast 1989-1994 includes catch from terminal gillnet fisheries.
3 Sport catches are for tidal waters only.
4 Outer WCVI sport catch from Area 23B (Barkley Sound)/Area 24 creel survey, July 15-Sept. 30, plus logbook catches. Terminal WCVI is catches in Alberni Inlet only.
5 GS sport catches from Areas 13-19, 28, 29 outside the Fraser River and are only estimated through October in 1994. Juan de Fuca Strait sport catches reported separately.
6 No creel survey was conducted in Johnstone Strait in 1994.
$7 \quad$ All WA inside sport numbers adjusted for punch card bias. See " 1988 WA State Sport Catch Report" for details.
${ }^{8}$ Strait troll catch includes all catch in Areas 5 and 6C and Area 4B outside the PFMC management period (Jan.-May and Oct.-Dec.).
9 San Juan net catch includes catch in areas 6, 6A, 7 and 7A; sport catch includes Area 7.
10 Coastal and Puget Sound sport catches include marine and freshwater, but only adults in freshwater.
${ }^{11}$ Columbia River net catches include Oregon, Washington and treaty catches, but not ceremonial.
12 Columbia River sport catches include adults only, for Washington, Oregon, Idaho and Buoy 10 anglers.
13 North of Falcon troll catch includes catch in Area 4B during the PFMC management period (May-Sept.), and Area 2.2 (Grays Harbor) when Area 2 is open.
14 Troll = late season troll off Elk River mouth (Cape Blanco); sport = estuary and inland (preliminary for 1994).

### 1.3 REVIEW OF FISHERIES WITH CATCH CEILINGS

### 1.3.1 Southeast Alaska (SEAK) Fisheries

In 1994, SEAK fisheries were managed under the following provisions:

1) An all-gear base-catch ceiling not to exceed 263,000 chinook salmon.
2) An Alaska hatchery add-on calculated on the basis of coded-wire-tag (CWT) sampling.
3) To maintain a total cumulative deviation in numbers of fish since 1987 within the $7.5 \%$ management range. For SEAK, the management range is equivalent to $+/-19,700$ chinook salmon for a ceiling of 263,000 . The cumulative deviation cannot be calculated for 1993 or 1994 due to lack of agreed PSC ceilings.
4) To comply with a 240,000 ceiling which was established during the U.S. Endangered Species Act (ESA) consultation with the National Marine Fisheries Service.
5) To be consistent with the provisions of the Pacific Salmon Treaty, as required by the Salmon Fishery Management Plan of the North Pacific Fishery Management Council, which was established by the U.S. Magnuson Act.

Catch data for 1994 indicate the following:

1) The 1994 all gear harvest (commercial and recreational) of 264,300 , including a hatchery addon of 31,800 , consisted of a commercial catch of 221,900 and a recreational catch of 42,400 .
2) The total estimated catch of Alaska hatchery produced chinook salmon was $39,000(14.8 \%$ of the total catch). The add-on was calculated by reducing this by 5,000 for the estimated preTreaty harvest of Alaska hatchery chinook and by 2,200 for risk adjustment.

### 1.3.1.1 Troll Fisheries

The troll fishery harvested a total of 186,300 chinook salmon of which $12,400(6.7 \%)$ were of Alaska hatchery origin. Catch data are summarized in Table 1-4.

Table 1-4. 1994 chinook catches in the SEAK Alaska troll fisheries.

| Troll Fishery | Total Catch | AKHatchery Catch | AKMatchery Percent |
| :---: | :---: | :---: | :---: |
| Winter Fishery (Oct. 11, 1993-Apr. 14, 1994) | 56,400 | 2,000 | 3.6\% |
| Hatchery Access (did not occur) | 0 | 0 | 0.0\% |
| Experimental and Terminal | 11,400 | 5,000 | 43.9\% |
| Summer Fishery (July 1-7, Aug. 29 - Sep. 2) | 118,500 | 5,400 | 4.6\% |
| Total Troll | 186,300 | 12,400 | 6.7\% |

As in 1993, the winter troll fishery began on October 11. The fishery operated as in past years and continued through April 14. The total winter harvest was 56,400 chinook, with 2,000 (3.6\%) from Alaska hatcheries.

Following the winter fishery, consultation occurred with NMFS in order to comply with the listing of Snake River Fall chinook salmon under the ESA. The Alaska Board of Fisheries eliminated the Hatchery Access fishery beginning in 1994. However, the experimental and terminal fisheries proceeded as usual. The experimental and terminal fisheries harvested 11,400 chinook, of which 5,000 (43.9\%) were Alaska hatchery fish.

The general summer troll fishery opened on July 1 for seven days. The fishery remained open from July 8 to August 26 with chinook nonretention (CNR). During this period, areas of high chinook abundance were closed to minimize incidental hook and release mortality. The fishery reopened with retention of chinook from August 29 to September 2. The fishery then remained open with CNR until September 20. From September 21 through September 30, waters outside the 3-mile limit closed to all fishing while waters within the 3-mile state jurisdiction remained open with CNR. In addition, portions of Districts $1,2,3$ and 4 were also closed. There were 12 days of chinook retention and 47 days of CNR. There were a total of 6,434 boat-days of chinook fishing effort and 35,718 boat-days of CNR.

### 1.3.1.2 Net Fisheries

The SEAK net fisheries have a guideline harvest of 20,000 non-Alaska hatchery chinook. The 1994 commercial net catch was 35,600 chinook, of which 17,200 (48.3\%) were from Alaska hatcheries. Of these hatchery chinook, 9,800 were taken in terminal area fisheries. Net harvest of chinook salmon in the purse seine fishery is limited by a $28^{\prime \prime}(70 \mathrm{~cm})$ size limit and the use of CNR regulations. Chinook between 21 " and 28 " may never be retained, while chinook below 21 " may be retained at all times. Gillnet harvest of chinook is limited by a delayed season opening.

### 1.3.1.3 Recreational Fisheries

The recreational fishery harvested 42,400 chinook, of which 9,400 (2.2\%) were from Alaska hatcheries. There was a one fish bag limit from April 15 to June 30. The bag limit was raised to two chinook from July 1 to July 29 and to three chinook on July 30. This fishery also has a $28^{\prime \prime}$ total length size limit.

### 1.3.2 North/Central British Columbia (NCBC)

Catch statistics for commercial fisheries are still preliminary for 1994, but no major changes are expected. The 1994 NCBC fisheries were managed under the following provisions:

1) An all-gear base-catch ceiling not to exceed 263,000 chinook salmon.
2) To maintain a total cumulative deviation in numbers of fish since 1987 within the $7.5 \%$ management range. For NCBC, the management range is equivalent to $+/-19,700$ chinook salmon for a ceiling of 263,000 . The cumulative deviation cannot be calculated for 1993 or 1994 due to lack of agreed PSC ceilings.
3) To manage the fisheries consistent with the spirit and intent of the Pacific Salmon Treaty and the chinook rebuilding program.

The estimated 1994 catch was 250,933 excluding terminal exclusions of 7,210 (Table 1-5).
Table 1-5. Proposed terminal exclusions.

| Area | Base | 1994 <br> Catch | $1994$ <br> Exclusion |
| :---: | :---: | :---: | :---: |
| Skeena | 2,900 | 7,559 | 4,659 |
| Bella Coola | 2,950 | 5,501 | 2,551 |
| Kitimat | 2,400 | Not Yet Available | 0 |
| Total 7,210 |  |  |  |

### 1.3.2.1 Troll Fisheries

The minimum size limit remained at 67 cm ( 26.5 inches fork length). The 1994 troll fishery opened for all species on July 1. By September 5 the chinook allocation was achieved and nonretention of chinook was in effect until September 14, when the north coast closed for the season. The reported catch in NCBC troll fisheries was 182,357 and involved nine days of CNR.

### 1.3.2.2 Net Fisheries

Catch of chinook in NCBC areas was 36,839 . Catches by fishery were 4,569 in the Queen Charlotte Islands, 17,759 for the Skeena/Nass and 14,511 in Central British Columbia (CBC). These are the preliminary total catches of chinook greater than 5 pounds, including the catch eligible for terminal exclusion.

### 1.3.2.3 Recreational Fisheries

The tidal water sport fishery catch of chinook was 38,947 . Catch by fishery was 28,973 for the Queen Charlotte Islands, 3,171 for the Skeena/Nass and 6,803 for the Central Coast.

### 1.3.3 West Coast Vancouver Island (WCVI) Troll

In 1994, the WCVI troll fishery was managed under the following provisions:

1) A base-catch ceiling not to exceed 360,000 .
2) To maintain a total cumulative deviation in numbers of fish since 1987 within the $7.5 \%$ management range. For WCVI, the management range is equivalent to $+/-27,000$ chinook salmon for a ceiling of 360,000 . The cumulative deviation cannot be calculated for 1993 or 1994 due to lack of agreed PSC ceilings.
3) To manage the fishery consistent with the spirit and intent of the Pacific Salmon Treaty and the chinook rebuilding program.

The minimum size limit for troll fisheries remained at 67 cm ( 26.5 inches) fork length. The 1994 troll season started on July 1 and continued until September 5 with no CNR fisheries. The conservation Areas A to E, G, H, I to L, F1 and F2 were opened at the start of the season, while Area $S$ remained closed (Figure 1-1).

When the troll fishery closed on September 5, it was estimated that 25,210 boat days had been expended during the season. This compares to 50,500 boat days for the 1985-1987 average. Chinook catch in 1994 for the WCVI troll fishery was 145,759.

### 1.3.4 Strait of Georgia (GS)

Chinook catch in 1994 for the combined GS troll and recreational fisheries was 83,805 but this total only accounts for recreational catch through October, 1994. Monitoring of this recreational fishery was limited due to continued budget reductions.

### 1.3.4.1 Troll

The minimum size limit remained at 62 cm ( 24.5 inches) fork length in the Strait of Georgia. The management objective was a domestic catch ceiling of 31,000 chinook. The ceiling was reduced to this level in 1988 to achieve a $20 \%$ harvest rate reduction, relative to 1987 levels, as part of a conservation plan for lower GS chinook. Troll fishery opened for chinook retention on July 1 and continued until September 15 without interruption. The 1994 GS troll catch was 12,966.

### 1.3.4.2 Recreational

The 1994 management objective for the GS recreational fishery was to maintain a $20 \%$ harvest rate reduction, relative to 1987 levels, on lower GS chinook. The management plan implemented in 1989 was continued in 1994. The plan's management actions are presented in Table 1-6.

Table 1-6. Strait of Georgia 1994 recreational fishery management plan.

| IfishmsArea | Daily Bay limila |  | Ammual Bag Limil |  |  | Stze Limit (cm) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{aligned} & 1989= \\ & {[1994} \end{aligned}$ | $\begin{aligned} & 1985 \\ & 1988 \\ & \text { and } \end{aligned}$ | $\begin{aligned} & 19899 \\ & 1994 \\ & \hline 1 \end{aligned}$ | 1988\% | $\begin{aligned} & 1985 \\ & 1987 \end{aligned}$ | 1989 1994 | $198 \%$ $1988 \%$ |
| Strait of Georgia (Areas 13-18, 19B, 28 \& 29) | 2 | 2 | 15 | 8 | 20 | 62 | 45 |
| Juan de Fuca (Area 19A) | 2 | 2 | 20 | 8 | 20 | 45 | 45 |
| Johnstone Strait (Area 12) | 2 | 4 | 15 | 30 | 30 | 62 | 45 |

The 1994 catch estimated from the creel survey in Areas 13 through 19, but excluding Juan de Fuca Area 19B+ and Johnstone Strait, was 56,467 through October. Fishing through October would be expected to account for at least $95 \%$ of the total year's catch, based on past creel survey data. Effort through October 1994 totaled 373,190 boat trips, which is very similar to 1990-1993 average effort levels $(408,361)$. Catch in Juan de Fuca Strait (inside Sheringham Point) was 14,372 in 1994 from an effort of 87,939 boat days, which is very similar to the 19901993 average effort of 85,569 .

### 1.4 REVIEW OF OTHER FISHERIES

### 1.4.1 Canadian Fisheries

### 1.4.1.1 Transboundary Rivers

Chinook catches in the Canadian gillnet fisheries were: Taku River, 2,065 chinook adults and 235 jacks, and Stikine River, 1,092 chinook adults and 159 jacks. The catch of chinook in these rivers is limited to incidental catch during fisheries targeting on sockeye salmon.

### 1.4.1.2 Southern British Columbia Fisheries

Commercial Net: The catch of chinook in the net fisheries is limited to incidental catch during fisheries targeting on sockeye, pink, or chum, with the exception of the August/September gillnet fisheries in Alberni Inlet (Area 23) and, in 1994, fisheries in Nootka Sound (Area 25). These fisheries are terminal gillnet fisheries for returns to the Robertson Creek Hatchery and Conuma Hatchery, respectively. Small numbers of chinook may also be harvested incidentally during gillnet and seine fisheries on sockeye salmon in Barkley Sound in July. Catches for 1994 are presented in Table 1-7.

Table 1-7. Southern British Columbia commercial net catches in 1994.

| Area (Statistical Area) | Cath (chimoolヶ5 lb.) |
| :---: | :---: |
| Johnstone Strait (11-13) | 8,968 |
| Strait of Georgia (14-19) and Fraser R. $(28,29)$ | 14,078 |
| Juan de Fuca Strait (20) | 8,932 |
| Barkley Sound (23) | 1,041 |
| Other WCVI ( $21,22,24-27)$ | 1,322 |

The management objective of southern B.C. net fisheries is to reduce the base period harvest rate on chinook by $25 \%$ (an obligation in the PSC chinook rebuilding program). Further, the Johnstone Strait net fisheries have the added objective of reducing harvest rates since 1987 by an additional $20 \%$ as part of the conservation program for chinook stocks in the lower Strait of Georgia.

In all the fisheries, regulations and research programs are attempting to limit the incidental mortality of juvenile chinook and coho. Fishing time, location, and gear are limited in southern B.C. net fisheries to conserve juvenile and adult chinook salmon. In Johnstone Strait and Juan de Fuca Strait, known areas of high chinook vulnerability are closed and minimum depth strata are set to reduce the catch of juvenile chinook and coho. In Juan de Fuca Strait, a maximum number of juvenile chinook and coho salmon per set has been established, beyond which the fishing area is further restricted or even closed. Chinook catch in the Fraser River area is usually limited to gillnet fishing and chinook catch is incidental. Also, in recent years gillnet fishing in the Fraser

River has been restricted to limit fishing time during September in order to restrict catch of Harrison River chinook returning to spawn.

Area 12 Troll: Catch is reported as 2,207 chinook for 1994. This fishery is a small localized group of trollers at the southern limit of Queen Charlotte Sound. The fishery is limited to a catch ceiling of 5,000 chinook, which is included in the overall WCVI catch ceiling of 360,000 .

Tidal Recreational: The outer WCVI sport fishery occurs primarily in the Barkley Sound area, outer Clayoquot Sound, and in Nootka Sound. The majority of the fishery effort occurs from mid-July through mid-September. A creel survey is conducted during the peak of this fishery from July 15 to September 30, corresponding to the return timing of Robertson Creek Hatchery chinook. The estimated catch in Barkley Sound area was 32,415 chinook; the catch in Alberni Inlet was 14,224 chinook. Problems in the 1994 creel survey in Area 24 (Clayoquot Sound) precluded estimation of catch in this area. Catch in Alberni Inlet is of Somass River stock only, and so is reported separately under terminal WCVI catch. No creel survey was conducted in Johnstone Strait in 1994.

Non-tidal Recreational: Non-tidal recreational fisheries occur in most B.C. rivers, including the Alsek, Skeena, Nass, Kitimat, Bella Coola, Somass and Fraser Rivers and various streams on the east coast of Vancouver Island. Most of these are small, localized fisheries to provide the local public with some access to salmon fishing. Recent fisheries in the Fraser River have been limited to the larger chinook populations that have responded well to the chinook rebuilding program and most are limited by catch ceilings.

Chinook catch was estimated as 197 in the Alsek, and 4,066 in northern B.C. rivers (Areas 1-10). Eleven small sport fisheries operate in the upper Fraser River. The 1994 catch was 2,475. Sport fisheries also occur in the Vedder-Chilliwack River and lower Fraser River mainstem but were not assessed.

Indian Fisheries: The catches in the 1994 Indian fisheries are summarized in Table 1-8. Each of these fisheries involves directed chinook fishing periods and the incidental catch of chinook during fisheries on other species. Small portions of the catch may be taken in marine waters, with the exception of the Stikine and Alsek catches. Catch in these fisheries is mostly limited by fishing time, but allocation to meet food fishing requirements is the first priority use of allowable catches. The Fraser River fisheries were managed for fixed allocations with the sale of catch permitted.

Table 1-8. Catches in the 1994 Indian fisheries.

| Fishing Areas | Aduli Catch | Jackeatch |
| :---: | :---: | :---: |

1 Catch includes jacks.
2 Fraser catch includes Harrison. Catch above Sawmill Creek estimated during sockeye fishing only.

### 1.4.2 Southern U.S. Fisheries

### 1.4.2.1 Strait of Juan de Fuca and the San Juan Islands

As in past years, management measures were taken in the Strait of Juan de Fuca and other mixed stock areas to protect depressed spring chinook stocks. No commercial fisheries were opened during the spring chinook management period (April 16-June 15). The recreational fishery was restricted by a 30 -inch maximum size limit for chinook effective during the spring chinook management period. The Strait of Juan de Fuca recreational fishery was closed from May 1 through October 31.

Forecasted low chinook and coho abundance resulted in severe restrictions placed on mixed stock fisheries that harvest chinook and coho. The Strait of Juan de Fuca treaty troll fishery in Areas 5 and 6 was closed between April 15 and October 31. Purse seine and reef net fisheries were restricted by a 28 -inch chinook minimum size limit. Seine fisheries targeting species other than sockeye and pink salmon were required to have a 5 -inch mesh strip to reduce the catch of small chinook. Gillnet fisheries had no chinook minimum size, but mesh size restrictions were used to reduce chinook catch. It was recognized that the combined actions for chinook salmon would also serve to protect depressed Canadian-origin chinook stocks (primarily Fraser River runs).

The preliminary estimate of the 1994 incidental chinook catch in the Strait of Juan de Fuca net fishery is 5,700 chinook, compared to 1,400 in 1993. In the San Juan Island fisheries, the incidental harvest of chinook was 13,700 in 1994 compared to 14,000 in 1993.

The Strait of Juan de Fuca tribal troll fishery harvested an estimated 2,800 chinook, compared to 9,800 chinook caught in 1993. This is a chinook directed fishery that has been greatly reduced in recent years. The previous 5-year (1988-92) average chinook catch in this fishery was 46,000 .

Note that tribal troll catch estimates from this area do not include tribal catch in Area 4B during the May 1 to September 30 PFMC management period; catches during this period have been included in the North of Cape Falcon troll summary.

In 1994, the Area 4B state waters fishery, which occurs after the PFMC fishery, was kept closed due to poor status of many coho stocks. No chinook were harvested in this fishery in 1993. The total 1994 recreational catch estimate for Areas 5 and 6 is 1,600 chinook. This catch is much reduced from the 1993 catch of 32,200 chinook due to the fishery closure extending from May 1 to October 31. The estimated recreational chinook catch in the San Juan Island fishery was 5,800 in 1994, compared to 6,900 in 1993.

### 1.4.2.2 Puget Sound

Recreational and commercial fisheries in Puget Sound were regulated by unprecedented time and area closures to protect depressed spring and fall chinook and coho stocks. As a result of restrictions or closures placed on mixed stock fisheries, some terminal runs contained hatchery surpluses or harvestable returns of wild fish. To protect depressed summer/fall stocks, there were no large directed chinook commercial net fisheries in the Skagit and Stillaguamish/Snohomish terminal areas; however, some tribal Ceremonial and Subsistence (C\&S) harvest occurred in these areas as well as an evaluation fishery to maintain annual fishery data. As was the case in the San Juan Islands, purse seine fisheries were restricted by a 28 -inch chinook minimum size limit. In seine fisheries other than those targeting pink salmon, a 5 -inch mesh strip was required to reduce the catch of small chinook. Gillnet fisheries had no chinook minimum size, but mesh restrictions were used to reduce chinook catch.

In 1994, the net catch of chinook continued to be low, although the total marine and freshwater catch was somewhat higher than the extremely low 1993 catch. Low catches were due to a combination of poor catch rates (in part due to low abundance) and management actions taken to protect both chinook and coho. Preliminary estimates of 1994 net catch in Puget Sound marine areas total 42,100 chinook, compared to 42,700 in 1993. Preliminary estimates of 1994 net catch in Puget Sound freshwater areas total 17,000 chinook, compared to 12,300 in 1993. Commercial marine catches in 1994 and 1993 represent only $41 \%$ and $42 \%$ of the previous 5 -year average (1988-1992) of 102,359 . Commercial freshwater catches represent $75 \%$ and $54 \%$ of the same 5 year average of 22,626 .

Puget Sound recreational fisheries were also managed with the intent to protect depressed wild chinook and coho stocks. As a result, recreational fisheries were limited by substantial time and area closures. Remaining fisheries were designed with the intent to harvest available hatchery surpluses. The Puget Sound marine recreational catch estimate for 1994 is 40,800 chinook, compared to a total of 41,000 in 1993. The freshwater recreational catch estimate is 3,400 , compared to 5,500 in 1993.

### 1.4.2.3 Washington Coast

Preliminary 1994 estimates of Grays Harbor and Willapa Bay net catch total 34,300 chinook, compared to 49,600 in 1993.

The 1994 commercial net fisheries in north coastal rivers have harvested an estimated 11,300 chinook, compared to 12,200 in 1993. Catches for the Humptulips and Chehalis rivers are included in the Grays Harbor marine net totals.

The 1994 recreational Willapa Bay and coastal river catch estimate is 7,000 chinook, compared to 9,700 in 1993.

### 1.4.2.4 Ocean Fisheries North of Cape Falcon

The U.S. ocean fisheries operating north of Cape Falcon, Oregon are typically constrained by coho and chinook quotas developed through the domestic regulatory process of the PFMC. In 1994, preseason forecasts indicated that many of Washington's critical chinook and coho stocks were expected to return at record low numbers. Many critical stocks were projected to return below spawning escapement goal levels, even in the absence of any 1994 fishing. In response to this unprecedented situation, extensive fishery closures were necessary in both preterminal and terminal areas to ensure the maximum return of these critical stocks to spawning areas.

All non-tribal recreational and commercial fisheries in the area north of Cape Falcon were closed in 1994. Ocean harvest North of Cape Falcon was limited to a tribal all-salmon-except-coho troll fishery during the period from May 1-June 30, 1994. This fishery had a quota of 16,400 chinook salmon. Effort and catch rates in this fishery were low and a total of 4,400 chinook were landed, which was $27 \%$ of the quota.

### 1.4.2.5 Columbia River

Since 1988, all in-river management of Columbia River fish runs and fisheries has been based on the Columbia River Fish Management Plan (CRFMP). "The purpose of this management plan is to provide a framework...to protect, rebuild, and enhance upper Columbia River fish runs while providing harvest for both Treaty Indian and non-Indian fisheries" (CRFMP, 1988, p.2). The CRFMP specifies management goals, season timing, catch limits, and maximum incidental impacts for all depressed upriver runs of anadromous fish in the Columbia River.

The 1994 in-river commercial catch of all chinook was 33,500, compared to 50,800 in 1993 and 53,200 in 1992. Preliminary freshwater recreational catch estimates for 1994 total 30,900 fish, compared to 82,500 in 1993 and 68,300 in 1992. The 1994 chinook catch in the Buoy 10 recreational fishery was zero due to a late opening of the fishery to protect early Columbia River coho and chinook nonretention in effect until early October.

The 1994 total catch of upriver spring chinook was 2,078 fish, consisting of 855 caught in the non-Indian sport and commercial fisheries, 1,115 caught in Zone 6 C\&S fisheries, and 108 caught in C\&S fisheries in Idaho. The Idaho C\&S catch includes both spring and summer chinook. The CRFMP provides that for upriver spring chinook run sizes less than 128,800 , the mainstem harvest below Bonneville Dam is limited to the 1983-1985 average impact (4.1\%) on the upriver run. However, due to ESA concerns, the Columbia River Compact chose to limit the lower river impact to a maximum of $3.2 \%$ of the run. Under the CRFMP, treaty C\&S fisheries in Zone 6 are limited to $7 \%$ of the run. Postseason estimates of 1994 impacts of lower river and treaty C\&S fisheries are $4.3 \%$ and $5.3 \%$ respectively. Lower river impacts were greater than preseason
expectations because the upriver spring chinook return of 21,000 was less than half of the preseason forecast of 49,000 adults.

There has not been a mainstem fishery targeting upriver summer chinook since 1964. In the past, incidental harvest of summer chinook occurred during commercial sockeye fisheries. However, no commercial sockeye fisheries have occurred below McNary Dam since 1988. There is a very small catch of summer chinook in the mainstem treaty C\&S sockeye fishery. The total 1994 catch of summer chinook in this fishery was 207 fish.

Commercial catch of Columbia River fall chinook in 1994 totaled 31,332 (1,658 in lower river non-treaty fisheries and 29,674 in treaty fisheries). An additional 5,700 fall chinook were caught in treaty C\&S fisheries. Management constraints for the 1994 fall season included achieving a Spring Creek Hatchery return of 7,000 adults and an adult management goal of 46,000 Upriver Bright chinook over McNary Dam. By agreement of the CRFMP parties, the Upriver Bright management goal at McNary Dam for 1994 was increased to 46,000 adults to account for increased broodstock hatchery needs and to provide additional protection for Snake River fall chinook.

### 1.4.2.6 Ocean Fisheries Cape Falcon to Humbug Mountain

Ocean fisheries off Oregon's coast harvest predominately a mixture of southern chinook stocks not involved in the PSC rebuilding program; these stocks do not migrate north into PSC jurisdiction to any great extent. Some stocks originating in Oregon coastal streams do migrate into PSC fisheries, including the Northern Oregon Coast (NOC) and Mid-Oregon Coast (MOC) stock aggregates. The NOC stocks are harvested only incidentally in Oregon fisheries (probably $<5 \%$ exploitation rate), while the catch distribution of MOC stocks in Oregon fisheries is thought to be much greater.

Catch statistics are readily available for only one population of the MOC group in a preterminal troll fishery. Recreational catch of these two stock groups occurs primarily in estuary and freshwater areas as mature fish return to spawn and are reported through a "punch card" accounting system. In 1994, the recreational chinook catch for the NOC and MOC groups was 28,400 and 8,600 , respectively. The troll catch in the late season preterminal Elk River Fishery was estimated to be 371 chinook, compared to 649 chinook in 1993.

## 2. ESCAPEMENT ASSESSMENT OF REBUILDING THROUGH 1994

### 2.1 INTRODUCTION

The Pacific Salmon Treaty (PST) established a system of fishery specific catch and harvest rate restrictions intended to:
"... halt the decline in spawning escapements of depressed stocks; and attain by 1998, escapement goals established in order to restore production of naturally spawning chinook stocks, as represented by indicator stocks identified by the Parties, based on a rebuilding program begun in 1984." (Annex IV, Chapter 3)

In this chapter, our objective is to use escapement data to evaluate the rebuilding status of naturally spawning chinook stocks with respect to these stated PST objectives of: 1) halting escapement declines, and 2) attaining escapement goals by 1998. It should be recognized that while coastwide chinook stocks were generally depressed before PST implementation, not all individual stocks were declining.

Because it was hoped that the decline in escapements would be quickly halted, most previous CTC analyses focused on evaluating the rate at which stocks were rebuilding to their escapement goals. However, as we near the end of the rebuilding program, it has become clear that many chinook stocks are at risk of failing to achieve their escapement goals by their rebuilding target dates. For these stocks, it is appropriate to ask, "Has the decline in spawning escapements at least been halted?" This question can also be asked of stocks without established escapement goals, even though rebuilding progress of these stocks can not be measured.

Escapement information has been compiled for a set of indicator stocks representing the majority of naturally spawning chinook stocks from central Oregon to Southeast Alaska (SEAK). Spawning escapements were assessed as one measure of rebuilding progress since implementation of management actions under the PST. Because escapements are a product of brood year adult abundance, freshwater and marine survival rates, and fishery harvest rates, the escapement assessment alone is not sufficient to determine if management actions since PST implementation have been effective in rebuilding chinook stocks. For a more complete picture, the results of this assessment should be considered together with the Exploitation Rate Assessment in Chapter 3.

The CTC used several methods to assess escapement declines and rebuilding progress for the indicator stocks. For stocks with escapement goals, the escapement assessment first identified stocks with escapements in recent years greater than their goals. For the remaining stocks with escapement goals, the assessment focused on: 1) comparison of recent escapements and the recent 5-year average escapement to a linear trend from the base period to the goal at the rebuilding target date, and 2) trends in recent escapements. This first portion of the assessment identified stocks that are and are not expected to rebuild by their target dates. For those not on schedule to rebuild, recent 5 -year average escapements were compared to base period escapements to see if escapement declines have been halted. Stocks without escapement goals were also evaluated to see if escapement declines have been halted.

Two different rebuilding schedules are recognized in the PST. For SEAK and Transboundary River (TBR) stocks, conservation actions began in 1981 as part of a 15 -year rebuilding program initiated by Alaska. The PST sets a target date of 1995 for the TBR Stikine and Taku stocks to achieve their escapement goals. For all other chinook stocks, the PST established a 15 -year rebuilding program beginning in 1984 with a rebuilding target date of 1998. Although not specified by the PST, for all SEAK and TBR stocks, the target date of 1995 has always been used for analytical purposes.

Caution should be used when comparing escapement levels or goals among stocks since escapements are measured in different units. Annual escapement estimates used were measures of total escapement, where available, or indices of escapement. Due to the use of indices, differences in escapements may not represent differences among stocks in population size, but trends in escapement within a stock should reflect population changes.

### 2.2 FRAMEWORK

### 2.2.1 Escapement Indicator Stocks

This year's assessment included 44 naturally spawning escapement indicator stocks. These 44 stocks represent distinct populations or management groups that originate from individual rivers or watersheds. Some stocks represent several populations aggregated by region and life history type. Distribution of the indicator stocks by run timing and area of origin is shown in Table 2-1.

Table 2-1. Distribution of escapement indicator stocks by run timing and area of origin.

| Area of Origin | Rum Timing: |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Spring | Spring/ Summer | Summer | Summerl Fall | Fall | Total |
| Southeast Alaska | 5 |  |  |  |  | 5 |
| Transboundary | 5 |  |  |  |  | 5 |
| North/Central B.C. | 1 | 3 | 3 |  |  | 7 |
| Southern B.C. | 1 | 1 | 1 | 1 | 3 | 7 |
| Washington/Oregon/Idaho | 3 | 2 | 2 | 3 | 10 | 20 |
| Total | 15 | 6 | 6 | 4 | 13 | 44 |

1 These run timings are determined by management agencies; criteria used for categorization may differ among agencies.

### 2.2.2 Escapement and Terminal Run Data

### 2.2.2.1 Data Sources

The escapement and terminal run data used in this report were provided by management agencies in each jurisdiction. Data for each stock are presented in Appendix A tables and Appendix B graphs. For the 28 stocks with terminal harvest or broodstock removal, Table 2-2 lists the sources of mortality included in estimates of terminal run size.

### 2.2.2.2 Estimation Methods

Methods of estimating escapement varied depending on river characteristics and agency resources. Most escapement estimates were measures of actual spawner abundance, where available, or estimates (or indices) of abundance measured at a point of migration beyond the effect of major fisheries. Estimates were made using weirs and counting fences, aerial or foot surveys, dam passage counts, electronic counting devices, or mark-recapture studies. Escapements of the two Oregon Coast stock aggregates are estimates of the density of spawners per river mile for standard survey areas. For some stocks, estimates of natural spawners are adjusted to make them a more representative measure of natural stock escapements:

1) Many of the Canadian escapement indicator stocks are influenced, to some degree, by enhanced production. In most cases, this enhancement is an integral part of the rebuilding program and may increase the rate of rebuilding compared to a natural population. However, to account for this enhanced production during assessment of chinook rebuilding, the Canadian Department of Fisheries and Oceans (CDFO) has employed two procedures:
a) Some streams with major enhancement programs are excluded from the escapement indices (e.g., Kitimat River in Area 6, Atnarko River in Area 8).
b) In streams with more limited enhancement, collected broodstock is excluded from the natural spawners recorded, although enhanced returns that spawn naturally are included in these numbers (e.g., Yakoun, Lower Strait of Georgia, and Harrison).
2) For the Columbia upriver spring stock, mainstem dam counts adjusted for hatchery fish were used. Annual estimates of the total number of hatchery fish returning to the Columbia River were deducted from the total return in order to estimate the natural return.
3) For the North Oregon Coast (NOC) and Mid-Oregon Coast (MOC) aggregates, surveys conducted in areas influenced by enhancement have been excluded.

Table 2-2. Terminal run composition for 28 stocks with broodstock removal, rack sales or terminal fisheries.

| Stock | Broon Stock IRacl Sales. | Commercial Net | Ceremonial Subsistence | Freshyater Sport |

$\checkmark$ : A fishery occurs or broodstock is collected, and the take is included in the terminal run size estimate.
NI: A fishery occurs or broodstock is collected, but the take is not included in the terminal run size estimate.
1 Because this report only presents unexpanded index escapement estimates for TBR rivers, terminal run size estimates are not reported; terminal catch estimates can be found in TBTC (1994). Sport catch is Canadian only.
${ }_{2}^{2}$ Includes catch from the River/Gap/Slough gillnet fishery.
3 WCVI terminal run size is not estimated.
4 Puget Sound estimates include reconstructed, stock-specific catches from Areas 8, 8a, 10, and 10a.
5 Escapement estimates include fish taken for brood stock.

### 2.2.2.3 Stock-specific Notes

Chilkat: This stock was removed from the 1990 rebuilding assessment when it was discovered through a 1991-1992 radio-tagging study that the previous index was not representative of the escapement to the entire Chilkat drainage. ADF\&G has estimated total escapement to the Chilkat drainage since 1991. It is anticipated that these estimates will continue and that, despite the lack of base period data, the Chilkat will be included in future assessments when sufficient new data are available. Available data for this stock are included in Appendix A.

Area 6 Index: Future inclusion of this stock is currently under review due to inconsistent escapement enumeration.

Harrison: Escapement estimates for the Harrison stock are only reported since 1984. Prior to 1984, estimates were based on visual counts of escapement. Since 1984, escapement has been estimated using an annual mark-recapture program. The two estimation methods are not comparable.

Stillaguamish and Snohomish River: All harvest of the Stillaguamish and Snohomish stocks occurs incidental to the harvest of other species (see Section 1.4.2). Run reconstruction methods are used to allocate incidental harvest between the two stocks. Management actions taken in the terminal area to protect the Stillaguamish stock have been in effect since 1985, but run reconstruction methods do not reflect these management changes. As such, reported Stillaguamish terminal run sizes (and thus terminal catches) for 1985-1994 are likely overestimated, while those for Snohomish are likely underestimated.

Quillayute summers: For this stock, escapements represent a composite of naturally spawning fish from the summer stock and strays from enhancement. The designation "summer" is used to distinguish this native stock from an earlier nonnative enhanced spring run. While the summer run is managed for natural production, run timing of the two stocks overlaps to some extent.

Oregon Coast (NOC and MOC): River-specific spawner density indices (peak fish/mile) are calculated from observations made at several survey sites. A simple unweighted average across all rivers in the aggregate is then used as the annual measure for this analysis.

### 2.2.2.4 Changes Relative to the 1993 Annual Report

There were five notable changes from the 1993 report (CTC 1994). Minor updates to catch and escapement data, including updates to preliminary estimates for the most recent years, are not described.

King Salmon: ADF\&G made corrections to the King Salmon historical escapement counts to make index counts prior to 1983 comparable to other counts.

Andrew Creek: ADF\&G made corrections to the Andrew Creek historical escapement counts to reflect the fraction of total escapement counted in the index.

Alsek: The Transboundary Technical Committee modified the historical database for the Klukshu index to correctly account for broodstock, sport, and aboriginal removals from the total weir count.

WCVI: The escapement indicators for the WCVI include the Marble, Tashish, Artlish, Kauok, Tahsis, Gold, and Burman rivers. In recent reports, one additional river was erroneously included in the index. Escapements to the rivers, based on the Canadian escapement database, were used in this index. Average values (one year before and one year after) were used for years with no data.

Lower Georgia Strait: The escapement indicators for Lower Georgia Strait have been revised and now include the Nanaimo and Cowichan rivers only. All years of the LGS escapement data have been revised to remove the Squamish River escapements. The Squamish was removed due to inability to maintain a quantitative estimation procedure within available funds. Visual estimation of escapement in this glacial system is not considered to be reliable or repeatable among years.

### 2.2.3 Escapement Goals

### 2.2.3.1 Origin of Goals

The escapement goals provided by each management agency define long-term stock rebuilding objectives. Most of these goals were established by the managing agencies for each stock. The Transboundary Technical Committee (TTC) jointly determined goals for the three major transboundary rivers in 1991 (TBTC 1991) based on an index system; the goals are not expanded to represent the river-wide drainages. Where possible, agency goals were based on estimates of stock productivity, usable spawning habitat, or other factors, and represent estimates of escapement levels that produce maximum average production or sustained harvest.

For many stocks, interim escapement goals were developed prior to 1984. When developing these goals, it was recognized that data were insufficient or of poor quality and there was a lack of stock specific biological information for establishing escapement goals. For example, Canadian goals are interim targets based on a doubling of base period average escapements and SEAK goals were based on the highest escapement observed prior to 1981. Some goals have changed since 1984 and other goals may change as new information is acquired. The CTC has adopted guidelines for the acceptance of new indicator stocks and the revision of existing escapement goals for use in the CTC rebuilding assessment (CTC Technical Note 9403).

Eight of the indicator stocks have no specific escapement goals: NOC, MOC, Deschutes, Quillayute fall, Hoh spring/summer, Hoh fall, Queets spring/summer and Queets fall. These eight stocks, referred to as stocks without goals, are discussed separately in this chapter. The Washington coastal stocks are managed for escapement floors and inriver harvest rates; when terminal runs are predicted to exceed the escapement floor, terminal fisheries are managed on the basis of stepped harvest rates.

### 2.2.3.2 Changes Relative to the 1993 Annual Report

Changes to the WCVI and Lower Georgia Strait escapement indices resulted in escapement goal changes, because escapement goals for Canadian stocks are calculated as double the base period average escapement. An adjustment to the escapement in one base period year for Upper Georgia Strait also resulted in a minor goal change.

### 2.2.4 Assessment Period

For assessment purposes, a base period and a rebuilding assessment period were established for each stock. Base and rebuilding assessment periods differ among stocks:

SEAK and TBR Stocks: For SEAK and TBR stocks, a 15 -year rebuilding program was initiated in 1981, prior to implementation of the PST. The target date for completion of rebuilding is 1995. For these stocks, the base period includes the years 1975-1980 and the rebuilding assessment period includes the years 1981-1994.

Harrison Stock: Since comparable pre-1984 escapement data are unavailable for the Harrison stock, the Harrison base period is defined as 1984 and the rebuilding assessment period includes the years 1985-1994.

All Other Stocks: For all other stocks, a 15 -year rebuilding program was established for the years 1984-1998. For these stocks, the base period includes the years 1979-1982 and the rebuilding assessment period includes the years 1984-1994.

### 2.3 METHODS

All methods used in the escapement assessment were identical to those used in the 1993 Annual Report (CTC 1994).

### 2.3.1 Stocks Without Escapement Goals

While it is not possible to assess rebuilding progress for stocks without escapement goals, these stocks were included in the evaluation of escapement declines. Halting escapement declines is a stated PST objective; however, a review of escapement data shows that, in 1985, some indicator stocks did not have declining escapements. For such stocks, the CTC interpreted the PST language to mean that escapements should not decline after the start of the rebuilding program. Thus, the evaluation of escapement declines includes some stocks with stable escapements prior to 1985 .

### 2.3.1.1 Evaluating escapement declines

To determine if escapement declines have been halted, the recent 5 -year average escapement was compared to the average base period escapement. The standard error of the mean was calculated for each stock, based on the stock's 1975-1994 escapements (or all available escapements within this period). The standard error was used as a measure of stock specific escapement variability. For stocks with recent average escapements more than one standard error below the base period average, it was concluded that escapement declines have not been halted. For stocks with escapement increases more than one standard error above the base period average, it was
concluded that escapement declines have been halted. For stocks with recent average escapements within one standard error of the base period average, escapement variation was too great and/or the change in escapements was too small to determine if declines have been halted. Plus or minus one standard error was used as an arbitrary cut off; the lack of independence among years of escapement data precluded use of significance testing.

### 2.3.1.2 Other stock characteristics

The results of the escapement decline evaluation are reported, as well as: base period average escapements; recent 5-year average escapements; and recent 5-year average escapements, expressed as a percent of the base period average. These are included to provide some information about where stock escapements are now, relative to where they were before implementation of the rebuilding program.

### 2.3.2 Stocks With Escapement Goals

The CTC's escapement evaluation of stocks with escapement goals was intended to: 1) separate those stocks that are on or ahead of their rebuilding schedules from those stocks that are behind schedule, 2) determine if spawning escapement declines have been halted for stocks that are behind schedule, and 3) provide information to facilitate evaluation of the stocks behind schedule.

This approach used three levels of evaluation. First, stocks that are above goal were identified. Second, stocks that are meeting their rebuilding schedule were identified using short term criteria that assess rebuilding progress. For those stocks judged not to be meeting their rebuilding schedules, a third level of evaluation was performed to determine if escapement declines have been halted and to summarize attributes of these stocks.

This three-level system was implemented as follows:

1) Stocks above goal were identified. These were stocks with at least four of the last five escapements at or above goal and recent 5-year average escapements equal to or greater than the goal.
2) For those stocks not above goal, those that were rebuilding were identified. This determination was made using the following three criteria based on data from the last five years.
a) Mean Criterion. A test value was calculated as the average of the 1990-1994 data points from the stock's base to goal line. This test value was then compared to the average observed escapement for the last five years. If the observed average was greater than or equal to the test value, a score of +1 was assigned. Otherwise, a score of -1 was assigned.
b) Line Criterion. Observed escapements were compared with the base to goal line. If, in three or more of the last five years, the actual escapements were on or above the base to goal line, then a score of +1 was assigned. Otherwise, a score of -1
was assigned.
c) Short Term Trend Criterion. If in at least four of the last five years an escapement exceeded the previous year's escapement, a score of +1 was assigned. If in at least four of the last five years an escapement was equal to or below the previous year's escapement, a score of -1 was assigned. Otherwise, a score of 0 was assigned.

The scores of these three criteria were then added, resulting in a total score ranging from +3 to -3 . Rebuilding classifications were assigned as follows:

| Total Score | Classification. |
| :---: | :---: |
| +2, | Rebuilding |
| 0 | Indeterminate |
| -2, -3 | Not Rebuilding |

Stocks were classified into four categories: Above Goal, Rebuilding, Indeterminate, and Not Rebuilding. Indeterminate stocks were further reviewed by the CTC and considered for a status change. After this review, all stocks classified as Rebuilding were considered to be on their rebuilding schedules, and no further assessment was performed.
3) Those stocks that were classified as Indeterminate or Not Rebuilding were further characterized. The third level consisted of an evaluation of whether or not escapement declines have been halted, and a tabulation of some stock characteristics.
a) Evaluating escapement declines. Escapement declines were evaluated in the same manner as for stocks without escapement goals (see Section 2.3.1).
b) Other stock characteristics. All of the stock characteristics presented for stocks without goals are also presented for stocks with goals (see Section 2.3.1). Also included are recent 5-year average escapements expressed as a percent of goal.

### 2.3.3 Comparison With Previous Years

Assessment results were graphed for the years 1987-1994 (using current assessment methods). A table was constructed to compare 1994 assessment results with 1993 results.

### 2.4 RESULTS

### 2.4.1 Stock Assessment

### 2.4.1.1 Stocks Without Escapement Goals

Escapement and terminal run data for stocks without escapement goals are graphed and tabled in the Appendices. Recent escapements and results from the evaluation of escapement declines are shown in Table 2-3. Escapement declines have been halted for 7 of the 8 stocks without escapement goals. The exception is the Queets Spring/Summer stock, for which it is not currently possible to conclude if the escapement decline has been halted or continues.

### 2.4.1.2 Stocks With Escapement Goals

Individual stock results for the rebuilding criteria are shown in Table 2-4, assessment scores and status are shown in Table 2-5. Stock escapements in 1994 ranged from 6\% (Columbia River springs) to $212 \%$ (Situk) of escapement goals (Table 2-5).

Table 2-3. Summary of recent escapement data and analysis for escapement decline for the eight natural chinook indicator stocks without escapement goals. $\mathrm{SE}=$ Standard Error of the mean for 1975-1994 escapements.

| Stock Name | Region | RumType | Esc. Floor | 1994 Esc. | Base Period Avg. Esc. | $\begin{aligned} & 1990-94 \\ & \text { Avge } \end{aligned}$ | 1990.94 A vg as\% of Base | SE of 1975. 94 Esces |

Chapter 2. Escapement Assessment

Table 2-5. Assessment scores and status through 1994 of the 36 natural chinook indicator stocks with escapement goals.

[^1]Additional stock assessment information can be found in Figure 2-1, Table 2-6, and Table 2-7. Figure 2-1 summarizes 1994 escapements, expressed as a percent of goal, to provide a snapshot of rebuilding progress. In 1994, 18 stocks had escapements less than $76 \%$ of goal and 11 stocks had escapements above goal. Table 2-6 summarizes the distribution of stocks among the four rebuilding categories. A combined summary across all stocks is provided, as well as separate summaries for SEAK and TBR stocks and for other stocks. In 1994, 14 (39\%) of the stocks with goals were Above Goal or Rebuilding, while 20 (56\%) of the stocks were Not Rebuilding. A list of final rebuilding status is shown in Table 2-7.

Figure 2-1 Summary of escapements in 1994, expressed as a percent of escapement goal, for the 36 escapement indicator stocks with escapement goals.

[^2]Additional information about those 22 stocks classified as Indeterminate or Not Rebuilding is shown in Table 2-8. Escapement declines have been halted for $6(27 \%)$ of these 22 stocks, while $8(36 \%)$ have shown continued escapement declines. For the remaining 8 stocks ( $36 \%$ ), it is not currently possible to determine if escapement declines have been halted or continue. Of the 22 stocks, 6 ( $27 \%$ ) had recent 5 -year average escapements that were below base period averages.

Figure 2-2 Distribution of stocks among rebuilding categories for the years 1987-1994. All years prior to 1993 were re-calculated using the methods implemented in 1993 and the new escapement goals.

### 2.5 STOCKS CONSIDERED FOR STATUS CHANGES

After the initial assessment, four stocks were classified as Indeterminate. The CTC examined each of these stocks and considered whether to change its status. The CTC decided to change the
status of both the Keta and Quillayute summers to Rebuilding. Both of these stocks have been above or only slightly below their escapement goals for at least the last seven years. The Thompson and Green remain in the Indeterminate category. Green terminal run has been above the goal in most recent years, although the goal has not been achieved in the last three years.

### 2.6 SUGGESTION FOR FUTURE EVALUATIONS

The CTC's present assessment of rebuilding, based on attaining escapement goals and the recent trends in escapements, has recognized limitations as exemplified in this 1994 evaluation. A stock's escapement may vary about its goal (e.g., the Unuk River, Appendix B-5), or may have shown substantial recovery since the implementation of rebuilding programs but remain slightly below the goal (e.g., the Taku River, Appendix B-4). These stocks would be classified as Not Rebuilding, just as stocks which are clearly Not Rebuilding (e.g., Smith Inlet or Harrison River, Appendix B). Some CTC members have proposed that the CTC incorporate an additional rebuilding assessment criterion based on the proportion of the maximum surplus production expected from recent escapements for each escapement indicator stock. A criterion based on production would be consistent with the ultimate rebuilding objectives of the PST chinook rebuilding program, i.e., "...attain by 1998, escapement goals established in order to restore production of naturally spawning chinook stocks."

Application of a production criterion would require an understanding of the relationship between adult production and spawning escapement for each indicator stock. Such relations are presently used by the CTC in the PSC chinook model and ADF\&G has presented examples of stockrecruitment relationships for some SEAK indicator stocks. A production criterion could assist in addressing the inherent variability in adult returns observed in chinook salmon, due to natural variation in survival and fishing impacts. The present escapement assessment criteria are sensitive to these fluctuations and result in some stocks changing classification categories each year. Annual reclassifications might be reduced by use of a production criterion. For example, ADF\&G presented an assessment of the production expected from the past five years of escapements to the Unuk River stock. Between 1990-1994, this stock has averaged $89 \%$ of its escapement goal but due to fluctuations about the goal, this stock is classified as Not Rebuilding. However, ADF\&G estimated that adult returns from these escapements would be expected, assuming average survival, to be $96 \%$ of the production if the escapement goal had been achieved in each year. This results from the compensatory nature of stock-recruitment relations and the multiple age classes of chinook.

An additional rebuilding criterion based on production assessment has potential for improving the present escapement assessment of rebuilding and should continue to be explored. It would explicitly address a primary task of restoring production from naturally spawning stocks and would incorporate total production in our assessments, in addition to examining trends in spawning escapements. However, there are concerns that have to be examined. For example, such assessments assume that the stated escapement goals are the escapement levels which maximize a stock's surplus production (i.e., potential yield). Many of the escapement goals used in CTC assessments are acknowledged to be interim goals used as management targets for rebuilding and the assessment of productivity in these natural stocks. If future production is projected from past production relationships, it may not account for changes in survival which
would affect future production, sustainable exploitation rates, and escapement levels. The CTC has noted that many indicator stocks have recently experienced poor marine survival (CTC 1994). The CTC recommends the development and evaluation of production criteria to determine if one should be incorporated in future rebuilding assessments, but can not, at this time, evaluate the merit of this suggestion.

## 3. EXPLOITATION RATE ASSESSMENT <br> Based on CWT Recovery Data Through Calendar Year 1994

### 3.1 INTRODUCTION

The Exploitation Rate Assessment relies on CWT release and recovery data from a set of indicator stocks to estimate: 1) harvest rate indices for the ceiling fisheries and the U.S. South ocean sport and troll fishery, 2) exploitation rate indices of indicator stocks for naturally spawning stocks harvested in nonceiling fisheries and not achieving escapement goals, 3) brood year exploitation rates and indices, and 4) the distribution of catch and total mortality among fisheries. Methods of calculating the SEAK troll fishery index were modified to incorporate stratification of the fishery and nonceiling fishery index methods were modified to account for terminal fisheries.

Most of the statistics reported in the Exploitation Rate Assessment are based on cohort analysis. Cohort analysis simply reconstructs the production of a CWT group by starting with the escapement, catch, and incidental mortality of the oldest age class and working backwards in time to calculate the total abundance of ocean age 2 chinook at the beginning of fishing. These reconstructions are based on CWT recoveries by stock, age, and fishery. Quantitative estimates of CWT recoveries are unavailable for some fisheries (Table 3-1).

Table 3-1. Fisheries for which CWT recoveries are not available for inclusion in fishery or nonceiling fishery indices.

| Chinook Bycatch in Non-Salmon Fisheries | Limited and qualitative sampling |
| :--- | :--- |
| WCVI Sport | No base period sampling |
| Johnstone Strait Sport | Incomplete sampling |
| Canadian Freshwater Sport | Incomplete sampling |
| Canadian Freshwater Net | Incomplete sampling |

### 3.1.1 Fishery Indices

It was expected when the PST was negotiated that catch ceilings and increases in stock abundance would reduce harvest rates in fisheries managed under PST catch ceilings. The fishery index provides a means to assess performance against this expectation. An index less than 1.0 represents a decrease from base period harvest rates while an index greater than 1.0 represents an increase. The relative magnitude of the change is the difference of the index from 1.0 .

Fishery indices are presented for both reported catch and total mortalities (reported catch plus estimated incidental mortality). Both are expressed as adult equivalents (AEQ), where the AEQ factor is used as an adjustment to reflect the proportion of fish of a given age that would, in the absence of fishing, subsequently leave the ocean to spawn. The total mortality index provides a consistent means of representing changes in reported catch and incidental mortalities, including those associated with regulatory measures such as minimum size limits and chinook nonretention (CNR) periods. Direct estimates of incidental mortality cannot be obtained from CWT recoveries; mortality estimates are computed using estimates of the proportion of fish less than the
size limit, the relative contributions of indicator stocks during periods of chinook retention, and estimates of the total number of encounters with chinook during CNR periods.

In the SEAK and NCBC fisheries, indices are presented for troll gear only although the ceilings are applicable to net and sport gear as well. As in past years, only the recoveries from the troll fishery were used because the majority of the catch, and the most reliable CWT sampling, occurred in these fisheries. Because the allocation of the catch among gear types has changed in some fisheries (e.g., the proportion of the catch harvested by the sport fishery has increased in the SEAK and NCBC fisheries), the indices may not represent the harvest impact of all gear types. The CTC is evaluating how to include other gear types in the indices for the SEAK and NCBC fisheries.

### 3.1.2 Nonceiling Fishery Indices

The passthrough provision of the PST requires that "the bulk of depressed stocks preserved by the conservation program ... principally accrue to escapement." The ambiguity of the passthrough definition, and the lack of direction from the PSC, have prevented the CTC from analytically assessing if this provision of the PST has been satisfied. As an interim measure, this report includes a nonceiling index previously suggested by the CTC (CTC 1991) as a measure of passthrough. The index compares the expected AEQ mortalities (assuming base period exploitation rates and current abundance) with the observed AEQ mortalities, by calendar year, over all nonceiling fisheries of a Party (Table 3-2). Index values greater than 1.0 for nonceiling fisheries indicate that the exploitation rates have increased relative to the base period. Consistent with Canadian commitments to reduce harvest rates by $25 \%$ for Canadian nonceiling net fisheries, the index should be evaluated with respect to 0.75 for the Canadian nonceiling net fisheries. The CTC is unable to include the WCVI sport fishery in the index at this time because of the absence of base period data.

The wild stocks subject to the passthrough provision were identified from the list of escapement indicator stocks provided in Chapter 2. A stock was included in the analysis if the following three conditions were met: 1) the escapement goal was not achieved, 2) the stock was harvested in nonceiling fisheries (the same criteria for inclusion were used as for the fishery indices, CTC 1989), and 3) an exploitation indicator stock with base period tagging and estimates of escapement existed in the stock group.

Many of the CWT stocks used to compute the index are subject to different terminal area fisheries than are the naturally spawning stocks that the index is intended to represent. In this year's report, methods of calculating nonceiling fishery indices were modified to incorporate terminal harvest of naturally spawning stocks. Details of the modifications are discussed in Section 3.2.1.2.

Table 3-2. Fisheries included in the nonceiling fishery index.

### 3.1.3 Brood Exploitation Rates and Indices

Brood year exploitation rates provide the best measure of the cumulative impact of fisheries upon all age classes of a stock. The rates are computed as the ratio of AEQ total mortality to AEQ total mortality plus escapement. The numerator may be partitioned into components for AEQ reported catch and AEQ incidental mortality, with each component occurring in either ocean fisheries or all fisheries. In order to simplify the interpretation of trends in the estimates of brood exploitation rates, a brood exploitation rate index was computed by dividing the brood exploitation rate in each year by the average brood exploitation rate in the base period. A regional index was computed as the average of the indices for stocks within a stock group. Stocks within a stock group are listed in Table 3-5. The base period in this instance is defined in terms of the primary brood years that contributed to fisheries in 1979-1982; base period brood years were 1976-1979 for all stocks but Quinsam (1976-1980) and SEAK/TBR Inside Migrating (1978).

The exploitation rate on the indicator stock may differ from the exploitation rate on the wild stock it represents if the indicator stock is of hatchery origin and subject to terminal fisheries directed at harvesting surplus hatchery production. In the case of the brood exploitation rate, this difference was addressed by computing a rate for ocean fisheries and a total for all fisheries. Ocean fisheries were defined to include marine sport and troll fisheries, and CWT recoveries of ocean ages 2 and 3 fish in all nonterminal net fisheries. By partitioning the fisheries in this way, the most appropriate measure of brood exploitation rates on wild stocks could be selected. The method selected for each exploitation rate indicator stock is given in Table 3-5.

### 3.2 ESTIMATION OF EXPLOITATION RATES

Of the 35 exploitation rate indicator stocks, only 18 were used to calculate fishery indices, nonceiling indices, and/or brood exploitation rates, and those analyses are in this chapter. Catch distributions for these 18 stocks and an additional 12 exploitation rate indicator stocks can be found in Appendix D. Five exploitation rate indicator stocks were not used in this year's limited analysis. Also, three stocks in Idaho (Sawtooth Spring, Rapid River Spring, and McCall Summer)
and one in Washington (Leavenworth Spring) are tagged as PSC indicator stocks but are not analyzed because of the limited number of recoveries in ocean fisheries.

The composition of exploitation rate indicator stocks is shown in Table 3-3, all PSC indicator stocks are listed in Table 3-4, and the analyses performed using each indicator stock are shown in Table 3-5. Additional information on the indicator stocks and tag codes used in the analyses is detailed in Appendix C. Extrapolation of results to similar stocks and/or generalizations about fishery impacts will only be appropriate to the extent that the indicator stocks are representative of the array of stocks harvested in the fisheries or the stock groupings which they represent. As in previous years, the indicator stocks are dominated by stocks which migrate to terminal areas during fall (Table 3-3).

### 3.2.1 Theory and Procedures

### 3.2.1.1 Modifications of SEAK Troll Fishery Index

The CTC uses fishery indices to reflect changes in fishery impacts relative to a base period (19791982). In recent years, concerns have been raised regarding limitations of the existing fishery index, in particular, the inability to incorporate CWT data for stocks lacking base period data and the potential difficulty of reflecting changes in stock exploitation resulting from changes in the conduct of fisheries. The form of the CTC fishery index itself limits consideration of stocks to those with adequate tagging during the base period. Fishing patterns for some fisheries have changed substantially. One of the most striking examples of this is the SEAK troll fishery where the catch during the winter season has increased, the spring fishery has been largely curtailed, and the summer season has become markedly shorter. Because stock complexes are dynamic throughout the year, impacts of the SEAK fishery have likely changed over time as season structure has been altered. To determine if different stock complexes are exploited during different times of year, the AWG examined concentrations (CWT recoveries of a given stock-age group) for several time-area strata for the SEAK troll fishery. Six strata with significant differences were found. The AWG evaluated a number of alternative estimators to determine if strata considerations and additional tag recovery data could be incorporated into a fishery index. Details of the AWG analysis will be documented in a separate report. A summary of results is presented here.

To evaluate the performance of alternative estimators for the fishery index, the AWG developed a computer model to simulate the harvest, escapement, survival, and sampling of CWTs. The model incorporated 15 tagged and untagged stocks and a set of nine fisheries. The simulations incorporated variability in survivals, harvest rates, stock distributions, and sampling rates to evaluate the performance of alternative estimators under a variety of situations. Other types of variability, such as maturity rates and abundance of initial cohort sizes, were also incorporated into the model. Two types of fisheries were evaluated: a nonstratified fishery, where the harvest rates vary proportionately over the catch strata, and a stratified fishery, where the distribution of the stocks and harvest rates vary disproportionately over the catch strata.

The AWG determined that a useful fishery index should reflect both changes in harvest rates and stock distribution. Three general, desirable characteristics were identified: 1) the index should measure changes in fishery harvest rates if the distribution of stocks is unchanged from the base period; 2) the index should have an expected value of 1.0 for random variation around the base period fishery harvest rate, cohort size, and stock distributions; and 3) the index should weight changes in stock distribution by abundance. The simulation model was designed to compare the fishery index estimates with a "true" value calculated from known values in the simulation. After exploring several alternatives, the AWG concluded that the best estimate for a fishery index would consist of the product of a fishery harvest rate index and an index of stock abundance weighted by average distribution (i.e., the proportion of a cohort vulnerable to the fishery). This estimate was selected as the "true" value, since it was the only one with all three desirable characteristics.

The simulation model was used to evaluate the performance of six fishery index estimators, as measured against this "true" value. The formulas for the true value and the six estimators are presented in Appendix E. True index values were calculated using the known values of harvest rate, abundance,
and distribution of the stocks. These true values were compared to the current CTC estimator and five alternative estimators. All estimators are based on CWT recoveries of tagged stocks. The performance of the six estimators was evaluated against four criteria: 1) the average deviation from the true value (or bias), 2) the average absolute difference from the true value, 3 ) the average squared deviation from true value (or MSE), and 4) average absolute error as a proportion of the true value. Relative performance of the estimators against these criteria was similar. The AWG relied upon MSE as the principal criterion for evaluating estimator performance.

Three estimators, the CTC fishery index (FI), the proportional harvest rate index (PFI), and the stratified proportional harvest rate index adjusted for untagged stocks (SPFI) had the smallest MSE under a variety of simulation scenarios. Variations in survival rates, sampling rates, and harvest rates affected the accuracy and precision of all estimators in a similar manner. The primary factor responsible for differences in estimator performance was the amount of variability in stock distribution (the proportion of a stock-age group that is vulnerable to a fishery). Each of the three estimators performed better than the others under certain circumstances. For a nonstratified fishery, the PFI was marginally better when the coefficient of variation (CV) of the distribution parameters was less than $70 \%$, and the FI performed increasingly better when the CV was greater than 100\% (Figure 3-1). For a stratified fishery, the SPFI had a consistently lower MSE than the FI for CVs less than $150 \%$, but the FI was consistently better for CVs greater than $150 \%$ (Figure 3-2). Both the SPFI and the FI performed better than the PFI for all levels of variability in the stratified fishery.

Figure 3-1. Effect of CV of fishery distribution parameters on MSE of fishery index estimators for a nonstratified fishery.

Figure 3-2. Effect of CV of fishery distribution parameters on MSE of fishery index estimators for a stratified fishery.

In order to choose the estimator most likely to have the best performance for SEAK stratified fisheries, the variability in the distribution of stocks was examined. Two rough measures of the CV for the distribution parameters were devised. One measure looked at the distribution of the CVs of the concentration of stock/ages in the SEAK troll fishery strata. Another measure consisted of the CVs of the estimated annual distribution parameters of the stock/age groups in the SEAK troll fishery strata about the average, accounting for the effect of measurement error due to variability in CWT recoveries. Both these indirect measures are believed to overestimate the underlying variability in stock distributions because measurement error and variation in other processes have not been accounted for. Both measures suggest that the true CV in the distribution of stocks in the Alaska troll fishery is likely less than $50 \%$. Therefore, the AWG selected the SPFI as the preferred estimator for the SEAK troll fishery. Note that in computing the SEAK troll fishery index, the absence of August-September fisheries in several years necessitated the consolidation of the August-September and July-outside catch strata. Although the CTC adopted the SPFI as the preferred fishery index for the SEAK troll fishery, the FI is also provided for purposes of comparison (Figure 3-3).

FI Total Mortality and SPFI Total Mortality for the SEAK Troll Fishery

Figure 3-3. Comparison of fishery indices for the SEAK troll fishery using the new stratified proportional fishery index (SPFI) and the CTC fishery index (FI).

The CTC continues to use the FI for fisheries except SEAK troll. The performance of alternative fishery indices for other fisheries could not be evaluated within the available time frame; future analyses will include: 1) development and evaluation of appropriate stratification criteria and proposed stratification for other fisheries, 2) development of methods to account for size limit changes (resulting in changes in vulnerability of younger age fish to the fishery), and 3) estimation of the CV of the distribution parameters of stock/ages in other fisheries.

### 3.2.1.2 Modifications of Nonceiling Fishery Indices

Nonceiling fishery indices are used by the CTC to assess the impacts on depressed naturally spawning stocks of fisheries not subject to PSC ceiling management. Computation of the index requires including both ocean and terminal (freshwater) fisheries into a single index. This is problematic in that exploitation rates for these fisheries are not additive because ocean and terminal fisheries are operating on different cohorts. The nonceiling index used by the CTC for the past several years avoided this problem by computing an index based on expected catches under base period exploitation rates. The previous nonceiling index was the ratio of actual catches of an appropriate Exploitation Rate indicator stock to catches of that stock expected under base period exploitation rates.

The problem with using the index as described above is that many of the CWT stocks used to compute the index are subject to different terminal area fisheries than are the naturally spawning stocks that the index is intended to represent. URBs, for example, are used to represent fishery impacts on wild stocks in the WACO stock group. However, URBs are subject to significant net and sport harvest in the Columbia River. Because of different run timing and harvest policies, the naturally spawning Columbia River Summer stock that the URB stock represents is not subject to these freshwater fisheries. The ocean exploitation of URBs can be used to represent Columbia River summers, but the freshwater harvest cannot. A similar problem occurs with the Grays Harbor fall stock. URBs are subject to Columbia River fisheries that do not affect the Grays Harbor stock, and the Grays Harbor stock is subjected to a terminal net fishery that does not impact URBs.

Since the exploitation rate indicator stock and the wild stock in many cases are not subject to the same freshwater fisheries, the CTC has only been reporting nonceiling indices based on the fisheries common to both stocks. This year the CTC revised the nonceiling index to include the effects of fisheries that only operate on the wild stock. The new index, like the old, is the ratio of 'actual' to 'expected' catch of the exploitation rate indicator stock. For mixed stock fisheries, actual and expected catches are computed the same way as for the old index. For terminal fisheries, however, the 'actual' catch is computed by applying terminal harvest rates of the wild stock (derived from outside sources) to the terminal population of the exploitation rate indicator stock. In other words, the 'actual' terminal catch is the catch of the exploitation rate indicator stock that would have occurred in the terminal area if the exploitation rate indicator stock had been subjected to the same harvest rates as the wild stock. 'Expected' catches in the terminal fisheries are computed by multiplying the terminal population of the exploitation rate indicator stock by the base period terminal harvest rates for the wild stock. The nonceiling index is the ratio of the 'actual' catch to the 'expected' catch of the exploitation rate indicator stock.

Nonceiling indices previously reported for the North Puget Sound summer/fall stock group are now reported for each stock.

### 3.2.2 Assumptions of the Analyses

Assumptions for the cohort analysis and other procedures used in the Exploitation Rate Assessment are summarized below. Detailed discussions of assumptions and parameter values have been reported previously (CTC 1988).

### 3.2.2.1 Cohort Analysis

The primary assumptions of the cohort analysis are:

1) CWT recovery data are obtained in a consistent manner from year to year or can be adjusted to make them comparable. Many of the analyses rely upon indices that are computed as the ratio of a statistic in a particular year to the value associated with a base period. Use of ratios may reduce or eliminate the effect of data biases that are consistent from year to year.
2) For ocean age 2 and older fish, natural mortality varies by age but is constant across years.
3) All stocks within a fishery have the same size distribution for each age and the size distribution at age is constant among years.
4) The catch distribution of sublegal-sized fish is the same as legal-sized fish.
5) Incidental mortality rates per encounter are constant and are equal to 30\% for troll and sport fisheries and $90 \%$ for net fisheries.
6) In the absence of an independent estimate of incidental mortality during nonretention periods, the procedure for estimating the mortality of CWT fish of legal size assumes that the stock distribution remains unchanged from the period of legal catch retention. Gear and/or area restrictions during the CNR fishery are believed to reduce the number of encounters of legalsized fish. To account for this, the number of legal encounters during the nonretention fishery was adjusted by a selectivity factor. A factor of 0.34 was used for the WCVI and GS troll fisheries. This value is the average selectivity factor calculated from 3 years of observer data in the Alaska troll fishery (Mel Seibel, pers. comm.). A factor of 0.20 is used in the NCBC troll fishery. This factor corresponds to the proportion of fishing areas that remain open during nonretention periods. Note that this parameter in itself is not used to estimate the number of encounters during the CNR period; instead, the selectivity parameter is used in conjunction with the gear days data presented in Appendix C. A selectivity factor is not required for the SEAK troll fishery since an independent estimate of encounters is used.
7) Maturation rates for broods for which all ages have not matured (incomplete broods) are equal to the average of the available estimates.

### 3.2.2.2 Fishery Indices

The temporal and spatial distributions of stocks in and between fisheries are assumed to be stable from year to year.

### 3.2.3 Reported Catch Versus Total Mortalities

Fishery indices are presented for both reported catch and total mortality. The difference between reported catch and total mortality is incidental mortality, which includes the mortality of legalsized fish in CNR fisheries and the mortality of sublegal-sized fish in retention and CNR fisheries. Management strategies have changed considerably for fisheries constrained by PSC catch ceilings. Regulatory changes that have been implemented include size limit changes and extended periods of CNR. Estimates of incidental mortality are crucial for assessment of total fishery impacts, yet they cannot be determined directly from CWT recovery data. Procedures to estimate these incidental mortality losses and incorporate them into the Exploitation Rate Assessment have been previously described (CTC 1988).

### 3.3 FISHERY INDICES FOR CELLING FISHERIES

### 3.3.1 Overview

Successful completion of the rebuilding program requires a substantial initial reduction in the harvest rates in ceiling fisheries combined with further reductions over time. The initial reduction
was expected to occur as a result of implementing a ceiling for each fishery that would reduce catches below pre-Treaty levels. Hence, if abundance remained stable or increased, the harvest rate would decline. Further reductions in harvest rates for PSC ceiling fisheries were expected as the rebuilding program progressed, due to decreases in harvest rates in previous years and increases in production resulting from higher spawning escapements.

Fishery indices provide a means to assess the effectiveness of the PSC ceilings in reducing harvest rates. The fishery indices were computed for both reported catch and total mortality. The total mortality index includes the mortality of legal-sized fish from CNR fisheries and from sublegal sized fish in the retention and CNR periods. Given a stable age structure, the fishery index for reported catch and the index for total mortality index should give similar results in the absence of regulatory changes that alter the ratio of reported catch to incidental fishing mortality (e.g., size limit changes, CNR fishing periods).

In 1994, fishery indices were below base levels in each PSC ceiling fishery (Table 3-6). Fishery indices for 1994 were reduced from base period levels by $24 \%$ in the SEAK troll, $30 \%$ in NCBC troll, and $43 \%$ in WCVI troll. For the Strait of Georgia troll and sport fishery, the 1994 fishery index was $9 \%$ below base period levels and near the 1985-1994 average index value. The 1994 fishery indices for SEAK troll, NCBC troll, and GS troll and sport are higher than the projected indices from the 1984 CTC chinook model. The 1994 fishery indices for WCVI are lower than the 1984 projections (see Figures 3-4 through 3-7).

Table 3-6 provides a summary of the fishery indices for reported catch and total fishing mortality for each year since 1985 as well as the 1985-1994 average. In addition, Figures 3-4 through 3-7 graph the indices for total mortality for PSC ceiling fisheries.

Estimates of the indices presented in this report for years prior to 1994 may differ from previous estimates, particularly for more recent years, due to a number of factors including: 1) addition of new stocks in the index, 2) revised estimates of nonretention mortality, 3) revised estimates of CWT recoveries, or 4) revised estimates of the cohort size for broods that were previously incomplete.

Table 3－6．Percent change from the 1979－1982 base period in the fishery index for reported AEQ catch，total AEQ mortality，and the 1979－1984 and 1985－1994 averages for these statistics．

Figure 3-7. Estimated fishery indices for reported catch and total mortality for the GS sport and troll fishery, and the projected indices from the 1984 CTC chinook model.

### 3.4 NONCEILING FISHERIES

Estimates of the nonceiling fishery indices for U.S. and Canadian fisheries are presented in Figures 3-8 through 3-14. Each figure provides the estimated indices for wild stocks represented by an exploitation rate indicator stock. For example, the LGS wild stock is represented by two exploitation rate indicator stocks (Puntledge and Big Qualicum; Table 3-3). Although the passthrough provision applies to all depressed wild stocks harvested in a nonceiling fishery, insufficient CWT recoveries were available to estimate the index for Canadian stocks in U.S. nonceiling fisheries and U.S. stocks in Canadian nonceiling fisheries. Nonceiling fishery indices could not be estimated for the Skagit Spring, Columbia Upriver Spring, and Harrison River stocks because of the absence of a suitable exploitation rate indicator stock.

For U.S. nonceiling fisheries, indices that are less than 1.0 indicate that exploitation rates have been reduced relative to the base period. For the Canadian nonceiling fisheries, indices that are 0.75 or less indicate that exploitation rates in nonceiling net fisheries have been reduced to the target of $25 \%$ below the base period. The WCVI sport fishery is not included in the index since estimated recoveries during the base period are not available. Since this fishery has grown since the base period, failure to include it may lead to an underestimate of the index.

Nonceiling indices previously reported for the North Puget Sound summer/fall stock group are now reported for each stock. When evaluated in this way, harvest rates for each stock are now consistent with passthrough in 1993 and 1994 (as estimated by applying the nonceiling index).

Since the CTC is frequently asked questions about the U.S. South ocean sport and troll fisheries (including the Strait of Juan de Fuca troll), the indices for these fisheries are presented separately in Figures 3-15 and 3-16. These fisheries are one component of the aggregate of U.S. nonceiling fisheries to which the passthrough provision is applicable, and are included in the nonceiling index discussed above. The indices for the U.S. South ocean sport and troll fishery are presented separately for Columbia River and Puget Sound stocks, since these stocks are harvested in different areas. Columbia River stocks are primarily harvested in fisheries off the coasts of Washington and Oregon while the Puget Sound stocks are primarily harvested in the Strait of Juan de Fuca.

Upper Georgia Strait Canadian Nonceiling Fishery Index

Figure 3-8. Estimated nonceiling fishery indices for the UGS stock in Canadian fisheries. Indices were not computed for 1987 and 1989 because escapement exceeded goal.

Lower Georgia Strait Canadian Nonceiling Fishery Index

Figure 3-9. Estimated nonceiling fishery indices for the LGS stock in Canadian fisheries.

Skagit Summer/Fall
U.S. Nonceiling Fishery Index

Figure 3-10. Estimated nonceiling fishery indices for the Skagit summer/fall stock in U.S. fisheries. An index was not computed for 1990 because escapement exceeded goal.

Figure 3-11. Estimated nonceiling fishery indices for the Snohomish summer/fall stock in U.S. fisheries.

Stillaguamish Summer/Fall U.S. Nonceiling Fishery Index

Figure 3-12. Estimated nonceiling fishery indices for the Stillaguamish summer/fall stock in U.S. fisheries.

Figure 3-13. Estimated nonceiling fishery indices for the Columbia River summer stock in U.S. fisheries.

Grays Harbor Fall U.S. Nonceiling Fishery Index

Figure 3-14. Estimated nonceiling fishery indices for Grays Harbor fall stock in U.S. fisheries. Indices were not computed for 1987-1990 and 1992 because escapement exceeded goal.
U.S. South Ocean Sport and Troll

Columbia River Stocks

Figure 3-15. Estimated fishery indices for reported catch and total fishing mortality for the U.S. South ocean sport and troll fishery for Columbia River stocks.
U.S. South Ocean Sport and Troll Puget Sound Stocks

Figure 3-16. Estimated fishery indices for reported catch and total fishing mortality for the U.S. South ocean sport and troll fishery for Puget Sound stocks.

### 3.5 BROOD EXPLOITATION RATES

Sections 3.5.1-3.5.7 provide estimates of the brood exploitation indices for each of the seven stock groups with an exploitation rate indicator stock. Also included, where available, are the projected brood year indices from the 1984 CTC chinook model. Projected indices are not available for all stock groups because the 1984 model included only four stocks.

Total mortality and reported catch brood exploitation rates declined in 1994 for all of the stock groups examined except LGS. Changes in brood exploitation rate indices relative to the base period varied widely between the seven stock groups examined. In four groups, exploitation rates based on total fishing mortalities presently indicate no reductions from the base period values (SEAK/TBR-I, WCVI, LGS, NPS-S/F). The three other groups (UGS, SPS-S/F, WACO) indicate about a 30 to $40 \%$ reduction in ocean exploitation rates relative to the base period. For three stocks, there are brood year exploitation rate projections from the 1984 CTC chinook model. The 1994 brood year exploitation rates for WCVI (Figure 3-18) and LGS (Figure 3-20) are higher than the 1984 projections. The 1994 brood year exploitation rates for WACO (Figure $3-23$ ) are lower than the 1984 projections.

### 3.5.1 Southeast Alaska/Transboundary Rivers Inside Stock Group (SEAK/TBR-I)

Figure 3-17. Estimated brood total exploitation indices for the SEAK/TBR-I stock group.

Table 3-7. Estimated brood total exploitation rates for Alaska Spring stock.

| Brood Year | 1978 | 1979 | 1980 | 1981 | 1982 | 1983 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Reported Catch | 0.42 | 0.32 | 0.30 | 0.33 | 0.40 | 0.34 | 0.38 | 0.33 | 0.53 | 0.36 | 0.34 | 0.28 |
| Total Mortality | 0.55 | 0.44 | 0.39 | 0.49 | 0.64 | 0.54 | 0.62 | 0.53 | 0.74 | 0.60 | 0.57 | 0.54 |

### 3.5.2 West Coast Vancouver Island Stock Group (WCVI)

The 1983 broods were not included in Fig. 3-8 due to difficulties in estimating incidental mortality. Current CTC procedures do not estimate incidental mortality well when survival rates are near zero, as was the case with the 1983 brood of the Robertson Creek indicator stock.

Figure 3-18. Estimated brood ocean exploitation indices for the WCVI stock group and the projected indices from the 1984 CTC chinook model.

Table 3-8. Estimated brood ocean exploitation rates for Robertson Creek stock.

| Brood Year | 1979 | 1980 | 1981 | 1982 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Reported Catch | 0.52 | 0.50 | 0.37 | 0.38 | 0.34 | 0.39 | 0.41 | 0.46 | 0.48 | 0.45 | 0.35 |
| Total Mortality | 0.67 | 0.66 | 0.54 | 0.64 | 0.44 | 0.49 | 0.52 | 0.60 | 0.64 | 0.69 | 0.64 |

### 3.5.3 Upper Strait of Georgia Summer/Fall Stock Group (UGS)

UGS Brood Total Exploitation Index

Figure 3-19. Estimated brood total exploitation indices for the UGS stock group.

Table 3-9. Estimated brood total exploitation rates for Quinsam stock.

| Brood Year | 1979 | 1980 | 1981 | 1982 | 1983 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 |

## C. 1 Introduction

The Exploitation Rate Assessment provided in Chapter 3 relies upon CWT release and recovery data and estimates of CNR mortality to estimate a variety of statistics for the exploitation rate indicator stocks. This appendix discusses the CWT groups used in the analysis, the brood years represented for each indicator stock, the sources of the recovery data, and the estimates of CNR mortality provided by the management agencies.

## C. 2 CWT Groups Used and Brood Years Represented

The brood years for which CWT groups are available for the indicator stocks as well as the youngest age and oldest age are provided in Table C-1. Tag codes used in the Exploitation Rate Assessment are listed by stock and brood in Table C-2.

## C. 3 Sources of CWT Data Used

Sources of CWT recovery data and expansion procedures employed in the Exploitation Rate Assessment are summarized below. In a few cases, small samples from commercial fisheries have resulted in very large expansion factors. To avoid very large expansion factors associate with small samples, expansion factors were constrained to the range of 1 to 50 .

## C.3.1 Canadian Commercial Fisheries

Estimated recoveries for commercial fisheries in Canada were obtained from the Mark-Recovery Database maintained by CDFO at the Pacific Biological Station.

## C.3.2 Canadian Sport Fisheries

Observed recoveries for sport fisheries in Canada were obtained from the Mark-Recovery Program (MRP) database maintained by CDFO at the Pacific Biological Station. As in the analyses of the previous three years, expansion factors were computed using the following procedures. Starting in 1980, recoveries made in GS and WCVI during the summer months (May-September) were expanded as documented in Kuhn et al. (1988). Recoveries made in other months were expanded using the average expansion factor for the summer period in the same recovery year. Recoveries in areas outside of GS or WCVI used the corresponding expansion factor for the average of GS and WCVI, unless an expansion factor based on creel survey data was available. Recoveries made prior to 1980 in GS continued to be expanded by the default value of four.

GS sport recoveries were expanded using these procedures because of potential tag expansion biases associated with inadequate sampling and infrequent overflights of the sport fishery during winter months. The application of GS expansion factors to sport recoveries in other areas was necessary because reliable catch and mark incidence estimates are normally unavailable for these areas.

As in last year's report, terminal sport recoveries for the Big Qualicum Hatchery stock have been removed from the Georgia Strait Sport (GSPT) catch region. Examination of sport location files in the CDFO Mark-Recovery Database identified that tags from the Big Qualicum River recovery location had been inconsistently recorded as freshwater or marine recoveries. Further, during this examination, a consistent pattern of terminal marine recoveries, off the mouth of the Big Qualicum River in late August and September, was identified. Recoveries from this time/area stratum have been almost exclusively of $B Q R$ origin. $B Q R$ recoveries in this terminal stratum and from freshwater sport fisheries have been removed from the GSPT catch region. The effect of this correction is to reduce the GSPT exploitation rate on this indicator stock; particularly during the base period when this correction had its greatest effect. However, since the CTC Fishery Index is created by dividing annual exploitation rates by the base period average values, these corrections tend to increase the Fishery Index values, for the BQR stock, compared to those reported prior to the 1993 Annual Report.

## C.3.3 Canadian Escapement

Escapement data for Canadian stocks were determined directly from hatchery records, from the Salmon Stock Assessment database at the Pacific Biological Station, and from documents prepared through the Canadian key stream program. Details regarding the source of escapement data for each of the three Canadian hatcheries used in the fishery index analysis are as follows:

Robertson Creek. A proportion of the tagged fish returning to the Robertson Creek Hatchery spawn in the Stamp River; however, fish in the river have been sampled only since 1984. These recoveries have not been included in the exploitation rate analysis because comparable sampling was not conducted in the base period. Because the exploitation rate analysis for this stock assumes that a consistent portion of the return enters the hatchery, the exploitation rate will be overestimated. Further, native catch in the Somass River has increased recently, but this fishery is not sampled for coded-wire tags or included in the exploitation rate analysis. This nonreported catch will result in an overestimation of ocean exploitation rates and an underestimation of the total exploitation.

Big Qualicum. Since 1971, escapement for the Big Qualicum River has been enumerated and checked for CWTs at a counting fence, with two exceptions. First, the early part of the run, which was allowed to spawn naturally, was enumerated but not sampled for CWTs prior to 1988. This was accounted for by expanding the sampled fraction of the run to represent the total run (expansions were stratified by adult and jacks). Second, a few hundred fish which spawn below the fence (which is less than one kilometer above tidewater) were not enumerated or sampled. Fish in this latter group which had a CWT are excluded from the analysis.

Quinsam Hatchery. The Quinsam Hatchery obtains brood stock primarily by seining spawning adults from both the Campbell River (the main river) and the Quinsam River (a relatively small tributary). Brood stock captures are examined for marks and are added to the estimates of CWT escapement to the rivers. These are also stratified by sex for the purposes of sample expansions and for adjustments for lost pins and no data recoveries. Chinook entering the hatchery have not been an important factor until 1989. In addition, hatchery staff have sampled the carcasses in the
river for CWTs from 1978 to 1983. Since 1984, escapement has been estimated by a mark recapture program (Andrew et al. 1988; Bocking et al. 1990; Bocking 1991; Firth et al., 1993; Shardlow et al. 1986). Estimates of the CWT escapement to each river were made by expanding the CWTs recovered during the dead pitch by the fraction of the estimated total escapement which was sampled. Both the escapement and the dead pitch were stratified by sex, combining adult and jack males into a single stratum. CWTs recovered during carcass recovery prior to 1984 were expanded by using the average fraction sampled from the period 1984 to 1990, stratified by river with both sexes combined.

## C.3.4 SEAK Fisheries

Recoveries from SEAK commercial fisheries were obtained from the MRP with the exception of recoveries in 1977 and 1978. The 1977 and 1978 commercial data and all estimated sport recoveries were obtained from ADF\&G.

Data anomalies were corrected using procedures discussed in Appendix II of the 1987 CTC Annual Report (CTC 1988). Two important adjustments are:

1) CWT recoveries from commercial fisheries were expanded to account for unsampled catches by multiplying by the ratio of the total catch to the sampled catch. For net and trap gear, adjustments were computed for a district or group of districts by calendar year. For troll gear, a single adjustment factor was used for all time and area strata.
2) CWT recovery data for the SEAK sport fishery during the 1979-1982 base period are of poor quality due to very limited sampling. The sport fishery sampling program expanded from 1983 to 1986, resulting in more reliable estimates in recent years. To estimate CWT recoveries for this fishery in years prior to 1987, sport recoveries were estimated from troll recoveries and the relative size of the sport and troll catch (CTC 1990).

## C.3.5 SEAK Escapement

Escapement data for the Alaska stock are provided by the following agencies: ADF\&G (Crystal Lake Hatchery and Deer Mountain Hatchery), National Marine Fisheries Service (NMFS) (Little Port Walter) and Southern Southeast Regional Aquaculture Association (SSRAA) (Carroll Inlet, Neets Bay, and Whitman Lake). Methods used to compute the escapement for SEAK tag groups are summarized below in instances in which modifications from the agency reported escapement data were necessary. The escapement to SSRAA facilities includes recoveries from cost recovery fisheries since the catch in these terminal area fisheries is not included in the Alaska ceiling.

SSRAA. Marks on fish returning to SSRAA hatcheries were sampled using one of two methods:

1) Random sampling of fish for marks was conducted throughout the return for defined time periods of variable length. The target number of marks in each time period was 200; however, the actual numbers varied and the number of fish examined for marks was not always recorded.
2) Marked fish were deliberately selected from the return during each time period. The number of fish examined to obtain this select sample was not recorded. These marked fish were then randomly sampled for approximately 200 CWTs.

Neither of these methods provides a usable estimate of mark incidence. Hence the recoveries by tag code for these hatcheries were estimated as follows:

1) The tagged recoveries in each sample were expanded by the marked to total release ratio and summed across tag codes.
2) The total return (tagged and untagged) during each time period was then multiplied by the proportion of the expanded sum which belonged to each tag code. These estimates were then summed for all the return periods to obtain a total estimated return for each tag code.
3) As a result of this estimation procedure, the return estimates for each tag code include both the marked and unmarked portions of the release. To estimate the number of returning tags, this total estimate was divided by the release ratio.

This method assumes that the survival of marked and unmarked fish was equal.
Crystal Lake. The recoveries by tag code were estimated by expanding the CWT recoveries to the total return (tagged and untagged) using the same procedure as the SSRAA with the two following modifications.

1) The procedure was stratified by sex with separate estimations done for males, females, and jacks.
2) The total return of CWTs was known for all years and was used instead of sample data. However, returns from brood year 1979 were not recorded by tag code. The recoveries by tag code were estimated in the following manner. For each return-year brood-year combination, the estimated escapement by tag code was the product of the total recoveries of the brood and the proportion of the tagged brood release that belonged to each tag code. This method assumes that all tag codes in a brood year had equal survival from release.

Deer Mountain. The recoveries by tag code were estimated by expanding the CWT recoveries to the total return (tagged and untagged) using the same procedure as the SSRAA with the two following modifications.

1) A small number of fish were recovered in personal use fisheries in Ketchikan Creek each year. In some years these fish were sampled for CWTs; however, in some years only estimates of the total personal use catch were made. In these years, the breakdown of the personal use catch by tag code was estimated using the tag code breakdown at the rack.
2) The total returns of CWTs at the rack was known for all years and was used instead of sampled data. However, returns from brood years 1978, 1979, and 1980 were not broken down by tag code in the return years 1980, 1982, and 1983. The recoveries by tag code for these broods were estimated in the same manner as the 1979 Crystal Lake recoveries.

## C.3.6 Southern U.S. Fisheries

Recoveries by Washington, Oregon, and California fisheries were obtained from the MRP database with the following exceptions: 1993 Columbia River tributary and terminal sport recovery data for Oregon fisheries were obtained from ODFW and 1994 Columbia River tributary and terminal sport data for Washington fisheries were obtained from WDFW. 1994 Puget Sound sport catch/sample expansion factors were obtained from WDFW.

Data were obtained directly from WDFW or ODFW only when those data had not yet been provided to CDFO through PSMFC. It should remain a high priority of all agencies to provide this information to PSMFC in a timely manner since the work of the CTC is slowed considerably when data must be sought and integrated from a number of individual agencies.

## C.3.7 Southern U.S. Escapement

Escapement recovery data for southern U.S. stocks were obtained from the MRP database with the following exceptions:

1) Recoveries for tribal facilities in Puget Sound and the Washington Coast for 1994 were obtained from the NWIFC;
2) Recoveries to the U.S. Fish and Wildlife Service (USFWS) Makah National Fish Hatchery in 1994 were obtained from the USFWS;
3) Columbia River Basin escapements to Oregon facilities for 1993 were obtained from ODFW. Columbia River escapements for 1994 to Washington facilities were obtained from WDFW; and
4) Pre-1982 escapement data for the Stayton Pond and Willamette Spring stocks and escapement for the Bonneville stock through 1982 were obtained from ODFW. Pre-1979 escapements for the Spring Creek stock were obtained from USFWS.

Methods for calculating dam conversion rates and interdam loss (IDL: one minus the dam conversion rate) did not change from the 1991 annual report (CTC 1992). Currently, the conversion from Bonneville Dam to McNary Dam for Columbia Upriver Brights and Hanford Wild (URBs) is calculated for the exploitation rate analysis as:

McNary Count
(Bonneville URBs) - (Zone 6 Comm Catch) - (Deschutes Turnoff)

Bonneville Upriver Bright counts are calculated by WDFW by first calculating the stock composition of all brights above Bonneville Dam (URBs vs. mid-Columbia brights or MCBs), and then applying the proportion of URBs in the upriver run to the Bonneville Dam counts of brights based on visual observation of skin color. Zone 6 commercial catches are taken from the Columbia River Status Report (ODFW \& WDFW 1993). Ceremonial, subsistence, and sport catches between Bonneville and McNary Dams are provided by Columbia River treaty tribes and WDFW. The number of fish returning to the Deschutes River is estimated annually by ODFW. Fish entering other tributaries below McNary Dam are not accounted for; this will result in a slight overestimate of IDL.

The Lyons Ferry Hatchery conversion rate is the product of the conversion rate of URBs and an additional conversion rate for losses between McNary Dam (the last dam before the Snake River) and Ice Harbor Dam (the first dam on the Snake River and where Lyons Ferry escapement is measured for the exploitation analysis). Estimation of conversion between McNary Dam and Ice Harbor Dam is complicated by extensive straying and fallback over Ice Harbor Dam. An estimate was calculated by averaging the Columbia River per pool conversion rate (from Bonneville Dam to McNary Dam) and the Snake River per pool conversion rate (from Lower Monumental Dam to Lower Granite Dam). Escapements of tagged fish above Ice Harbor Dam, tag recovery rates and Snake River conversion rates were used to estimate total escapement of tagged Lyons Ferry Hatchery fish at Ice Harbor Dam.

## C. 4 Estimates of Incidental Catch Mortality

Fishery-specific estimates of incidental mortality or parameters used to estimate incidental catch mortality have been provided by regional management agencies and are listed in Appendix tables C-3 through C-8.

Table C-1. Brood years included by stock for Exploitation Rate Assessment

\end{tabular}

1 Adjustment of the CNR encounters was necessary in some years when little or no landed catch was present in the Fall fishing strata. The cohort analysis requires landed catch in a fishery with CNR encounters in order to estimate the CNR by tag code. The Fall CNR encounters from these years were redistributed to the corresponding Inside July or Outside July fishing strata to avoid this problem.

Alaska Dept. Fish and Game and National Marine Fisheries Service. 1987. Associated fishing induced mortalities of chinook salmon in southeast Alaska. Alaska Dept. Fish Game, unpublished report.

Davis, A., J. Kelley, and M. Seibel. 1986. Observations on chinook salmon hook and release in the 1985 southeast Alaska troll fishery. Alaska Dept. Fish Game, unpublished report.
The total CNR encounter estimates for each year were distributed to each stratum which had CNR by multiplying the total encounter estimate for the year by the proportion of the total CNR effort that occurred in the stratum.

Davis, A., J. Kelley, and M. Seibel. 1987. Observations on chinook salmon hook and release in the 1986 southeast Alaska troll fishery. Alaska Dept. Fish Game, unpublished report.

Seibel, M., A. Davis, J. Kelley, and J.E. Clark. 1988. Observations on chinook salmon hook and release in the 1987 southeast Alaska troll fishery. Alaska Dept. Fish Game, unpublished report.

Seibel, M., A. Davis, J. Kelley, and J.E. Clark. 1989. Observations on chinook salmon hook and release in the 1988 southeast Alaska troll fishery. Alaska Dept. Fish Game, unpublished report.

Data collected from a limited survey of the chinook nonretention fishery in 1989 indicated that encounter rates were similar to those which had occurred in previous years. For this reason, the number of encounters was estimated by multiplying the 1985-1988 average CNR encounters per gear day times the gear days for 1989. (Spreadsheet CNR90.WQ1, J. Carlile ADF\&G, 2/2/91)

The number of legal and sublegal encounters during the CNR fishery in 1990-1994 were estimated from a linear regression on the number of boat days of CNR effort.

Table C-4. Sources and estimates of legal and sublegal encounters in the SEAK net fishery during chinook nonretention fisheries.

\end{tabular}

1 Anonymous. 1986. Data Report on Unaccounted for Sources of Fishing Associated Mortalities of Chinook Salmon in B.C. Fisheries (1977-1986). Canadian Department of Fisheries and Oceans, unpublished report. 47p. Data reported is number of encounters.
\({ }^{2}\) Computed by multiplying the number of days during the chinook retention fishery by the ratio of the number of boat days during the nonretention fishery to the number of boat days during the chinook retention fishery.

\section*{APPENDIX E: FISHERY INDEX EQUATIONS}

\section*{Table of Contents}
E. 1 Notation ..... 1
E. 2 True Index ..... 1
E. 3 Estimated Indices ..... 1

\section*{E. 1 Notation}

\section*{Variables}
\(\mathrm{H}=\) Harvest Rate
\(\mathrm{D}=\) Stock Distribution (proportion of cohort vulnerable to a fishery)
\(\mathrm{N}=\) Cohort Size
C = Catch (expressed in either nominal or adult equivalent terms)
Subscripts
\(\mathrm{s}=\) stock-age class
\(\mathrm{B}=\) base period
\(\mathrm{yr}=\) index year
\(\mathrm{f}=\) fishery
\(\mathrm{k}=\) tagged stocks
\(\mathrm{u}=\) untagged stocks

\section*{E. 2 True Index}
\[
\mathrm{F}=\left(\frac{\mathrm{H}_{\mathrm{yr}}}{\mathrm{H}_{\mathrm{B}}}\right) \frac{\sum_{\mathrm{s}} \mathrm{D}_{\mathrm{s}, \mathrm{yr}} \mathrm{~N}_{\mathrm{s}, \mathrm{yr}}}{\sum_{\mathrm{s}} \mathrm{D}_{\mathrm{s}, \mathrm{~B}} \mathrm{~N}_{\mathrm{s}, \mathrm{yr}}}
\]

\section*{E. 3 Estimated Indices}

The Average Index is the average ratio of exploitation rates:
\[
\operatorname{avg}_{\mathrm{s}} \frac{\left(\frac{\sum_{\mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}}}{\hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{yr}}}\right)}{\left(\frac{\sum_{\mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}}}{\hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{~B}}}\right)} .
\]

The Straight Index is the ratio between the total exploitation rate of all stock-age groups in a given year compared to the base period average total exploitation rate of all stock-age groups:

The CTC Fishery Index (FI) is the ratio between stock-age specific exploitation rates during a given year and the base period averages for corresponding stock-age groups during the base period:
\[
\frac{\sum_{s}\left(\frac{\sum_{\mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}}}{\hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{yr}}}\right)}{\operatorname{avg} \sum_{\mathrm{s}}\left(\frac{\sum_{\mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}}}{\hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{~B}}}\right)} .
\]

The proportional fishery index (PFI) reflects the ratio between an estimated harvest rate during a given year and the base period average harvest rate. Harvest rates are estimated using an average stock distribution:
\[
\left.\frac{\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}}}{\sum_{\mathrm{s}} \hat{\mathrm{D}}_{\mathrm{s}} \hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{yr}}}\right)}{\operatorname{avg}\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}}}{\sum_{\mathrm{s}} \hat{\mathrm{D}}_{\mathrm{s}} \mathrm{~N}_{\mathrm{s}, \mathrm{~B}}}\right.}\right) .
\]

When fisheries are stratified, the proportional fishery index (PFI) can be estimated based on data for tagged stocks:
\[
\frac{\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}}}{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{yr}}}\right)}{\operatorname{avg}\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}}}{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{~N}}_{\mathrm{s}, \mathrm{~B}}}\right)} .
\]

However, the fishery affects both tagged and untagged stocks. The fishery index based on both tagged and untagged stocks (SPFI) can be expressed as:
\[
\hat{\mathbf{F}}=\frac{\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}(\mathrm{k})}+\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{yr}(\mathrm{u})}}{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{k})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{yr}(\mathrm{k})}+\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{u})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{yr}(\mathrm{u})}}\right.}{\operatorname{avg}\left(\frac{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{k})}+\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{u})}}{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{k})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{~B}(\mathrm{k})}+\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(u)} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{~B}(u)}}\right)} .
\]

In this index, no data are available to directly represent tagged stocks. The numerator in each term of the ratio simply represents total catch. The quantities
\[
\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{u})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{yr}(\mathrm{u})} \quad \text { and } \quad \sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{u})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{~B}(u)}
\]
are unknown. These quantities can be estimated using the assumption that harvest rates are the same for all vulnerable populations of stock-age groups. For example, for the base period
\[
\hat{\mathrm{H}}_{\mathrm{f}, \mathrm{~B}}=\frac{\sum_{\mathrm{s}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{k})}}{\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(\mathrm{k})} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{~B}(\mathrm{k})}}
\]

Therefore,
\[
\sum_{\mathrm{f}} \frac{\sum_{\mathrm{s}} \hat{\mathrm{C}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(u)}}{\hat{\mathrm{H}}_{\mathrm{f}, \mathrm{~B}}}=\sum_{\mathrm{s}, \mathrm{f}} \hat{\mathrm{D}}_{\mathrm{s}, \mathrm{f}, \mathrm{~B}(u)} \hat{\mathrm{N}}_{\mathrm{s}, \mathrm{~B}(u)}
\]

A similar estimate can be generated for untagged stocks in the index year. These values can then be substituted into the original formulation for the SPFI.```

[^0]:    Cumulative deviations calculated for 1987-1992, in absence of 1993-1994 PSC catch ceilings.
    Percent deviation calculated from base ceiling level. Negative deviations below the $7.5 \%$ management range are not accumulated.
    Due to budget constraints, catch in the Strait of Georgia sport fishery was only estimated through September in 1993 and October in 1994.
    There were no PSC ceilings agreed to in 1993 or 1994. Management regimes for 1994 ceiling fisheries are discussed in Section 1.3.

[^1]:    1 The status of these stocks was changed from Indeterminate due to stock-specific circumstances.
    2 Changes between the Rebuilding and Above Goal categories are not footnoted.

[^2]:    1 Status of these stocks was altered from Indeterminate (see text for details).

[^3]:    1 Stocks with an Indeterminate rebuilding status. Blossom escapements and goal are index numbers.

[^4]:    NC Index = index for nonceiling fisheries; Brood Exp = brood exploitation rates; Esc = quantitative estimates of escapement.
    1 Acronyms and descriptions for stock groups:

    | SEAK-TBR/I: | SEAK and Transboundary rivers, inside migrating |
    | :--- | :--- |
    | NCBC: | NCBC spring/summer |
    | WCVI: | WCVI fall |
    | UGS: | UGS summer/fall |
    | LGS: | LGS fall |
    | LFR: | Lower Fraser fall |
    | NPS-S/F: | North Puget Sound summer/fall |
    | SPS-S/F: | South Puget Sound summer/fall |
    | NPS-Sp: | North Puget Sound spring |
    | CRT: | Columbia River Tule hatchery stock |
    | WACO: | Washington Coastal Spring/Summer/Fall, non-Tule Columbia River Fall, North Oregon Coast, and Mid-Oregon Coast. |

    Only hatchery rack recoveries are included in escapement.
    Harrison stock only.
    Hatchery stock not used to represent wild stock.
    5 Not used in this year's analyses.
    6 Lists the appropriate statistic to consult when using the indicator stock to represent the regional stock group.
