## Acknowledgements

The analysis for this report was completed primarily due to the extensive efforts of Gary Morishima (model coding), Dell Simmons (model validation and model runs), John Carlile (summary tables), and Jim Scott (report compilation). The CTC extends its thanks to each of them for the large contribution that they made toward completing this assignment.

### 1.0 Introduction

In February of 1998, the United States (U.S.) and Canada exchanged proposals for abundancebased management regimes for chinook salmon. While many aspects of the proposals are similar, conceptual and technical differences exist. To identify and determine the significance of those differences, the Commissioners asked a bilateral workgroup to provide responses to a list of expository questions (see TCChinook (98)-01) and to conduct a retrospective analysis of the proposals. The retrospective analysis simulates the effects the proposed regimes would have had upon the fishing mortality, exploitation rates, and escapement of chinook salmon if the regimes had been in place from 1985 through 1996.

Briefly, both the U.S. and Canadian proposals include: 1) an abundance-based management approach for chinook salmon that includes limits for mixed-stock ocean fisheries (aggregate abundance-based management (AABM)) and constraints for the remaining fisheries (individual stock-based management (ISBM)); 2) provisions for adjusting allowable harvests in response to stock status; 3) a list of technical assignments; 4) approaches to reduce incidental mortalities; and 5) provisions for terminal exclusions, hatchery add-ons, and overage/underage policies.

The Chinook Technical Committee (CTC) has developed a version of the Pacific Salmon Commission (PSC) chinook model that provides the capability to simulate many features of the U.S. and Canadian proposals for AABM and ISBM regimes. Most importantly, the model now allows the specification of a set of rules that establish fishery specific impact limits that vary by year in response to the abundance of chinook salmon. The rules used by the CTC in this analysis are based upon our interpretation of the proposals (as assisted by the Commissioners during bilateral deliberations in December, 1998). However, not all features of the proposed regimes are currently simulated, nor are all factors affecting chinook salmon fishing mortality and escapement considered. Important limitations of the analysis include the following:

Survival Rates. The retrospective analysis does not address the question "What will be the effects of the proposed regimes on fishery catches and escapement in future years". Catch and escapement in the future will depend to a large extent on the effects of the freshwater and marine environment on chinook salmon survival rates. Survival rates for most stocks are currently substantially less than the rates for broods that were harvested in the late 1980s.

Stock Status. Provisions for adjusting fishery impacts in response to stock status are not simulated. This decision was driven by several factors: 1) the provision is not fully developed in the Canadian proposal; and 2) interpretation of the U.S. proposal is difficult, and implementation occurs "only for those stocks for which the escapement goal review has been completed and the escapement goal agreed to." The escapement goal review has not yet been completed by the CTC.

Fishery Impacts. Simulated fishery impacts are identical to the target catch or mortality in each year. In practice, uncertainty in predictions and management error will result in impacts that differ from the target values.

Time Stratification. The PSC chinook model does not currently have the capability to assess changes in stock composition, abundance, or exploitation rates at a time step finer than one year. Therefore, analysis of the Canadian proposal for the West Coast Vancouver Island (WCVI) and North of Leadbetter Point (NLP) troll fishery was predicated on the understanding that the total allowable mortalities would be computed based on the aggregate abundance of chinook available on an annual basis to the WCVI and NLP troll fisheries (see June 12, 1998 letter from the CTC to the chairs of the PSC).

Fishery Stratification. Fisheries in the PSC chinook model generally correspond to those identified in the U.S. and Canadian proposals. One exception is the NLP troll fishery referenced in the Canadian proposal. The closest approximation in the PSC chinook model, and the fishery used as a surrogate in the CTC analysis, is the U.S. south ocean troll fishery. This model fishery includes all troll fisheries off the coasts of the states of Washington, Oregon, and California that impact stocks from Puget Sound, the Washington Coast, the Columbia River, and far north migrating stocks from the Oregon coast (see June 12, 1998 letter from the CTC to the chairs of the PSC).

### 2.0 Simulation of Proposed Regimes

The CTC simulated the proposed regimes using a retrospective analysis for the years 1985 through 1996. The retrospective analysis examines the effects the proposed regimes would have had upon the fishing mortality, exploitation rates, and escapement of chinook salmon if the regimes had been in place from 1985 through 1996. A retrospective, rather than forward analysis, was used because of uncertainty in future survival rates, and the limited capabilities of the current version of the PSC chinook model to simulate multiple scenarios for survival rates.

The CTC retrospective analysis includes two variants of each Party's proposal, with the variants differing in the management regime applied to the ISBM fisheries. Previous discussions within the CTC indicated that substantial uncertainty existed in the interpretation of both the U.S. and Canadian proposals for the ISBM fisheries (see TCChinook (98)-01). This uncertainty led to a recommendation by the CTC that each proposal be modeled with ISBM fisheries at both actual fishery levels and at a $25 \%$ reduction from the 1979 through 1982 base period. This recommendation was accepted by the commissioners at the December, 1998 Executive Session of the PSC.

The results from the simulation of the proposals are compared with a benchmark, the 1998 preseason calibration of the PSC chinook model. The benchmark run and four retrospective model runs are summarized below and discussed in greater detail in Section 2.1:

Benchmark provides the base against which to compare the results from the proposed regimes. The Benchmark run includes the estimates of stock productivity, escapements, fishery catches, chinook non-retention mortality, and sublegal chinook mortality used by the CTC in the 1998 preseason calibration of the PSC chinook model (calibration 9812).

US-Act simulates the U.S. proposal for AABM fisheries in combination with the actual post-season estimates of exploitation rates in the U.S. proposed ISBM fisheries.

US-25 simulates the U.S. proposal for AABM fisheries in combination with exploitation rates in the U.S. proposed ISBM fisheries reduced by $25 \%$ from the 1979 through 1982 base period ${ }^{1}$.

Can-Act simulates the Canadian proposal for AABM fisheries combined with actual post-season estimates of exploitation rates in the Canadian proposed ISBM fisheries.

Can-25 simulates the Canadian proposal for AABM fisheries combined with exploitation rates in the Canadian proposed ISBM fisheries proposed reduced by $25 \%$ from the 1979 through 1982 base period ${ }^{1}$.

[^0]
### 2.1 Computation of Allowable Impacts and Allocation Among Fisheries

### 2.1.1 U.S. Proposal

The U.S. proposal identifies four regions in which to apply AABM, and each region can include up to five fisheries:

1) Southeast Alaska (SEAK) - SEAK troll, SEAK sport, and SEAK net
2) North/Central British Columbia (NCBC) - North British Columbia (NBC) troll, NBC net, Central British Columbia (CBC) troll, CBC net, and NCBC sport
3) WCVI - WCVI troll and WCVI outside sport
4) Strait of Georgia (GS) - GS troll and GS sport

The U.S. proposal provides explicit procedures for relating an abundance index (AI) and a harvest rate index (HRI) to compute the total allowable catch for AABM fisheries within a region, but does not specify the allocation of that catch among gear types (Table 1). With the exception of the SEAK fisheries, the CTC chose to allocate the total allowable catch based on the average proportion of the catch taken by each gear type in the years 1985 through 1996. For the SEAK fishery, 20,000 fish were allocated to the net fishery, and the sport fishery catch was set to $25 \%$ of the troll fishery catch (Table 1).

The ISBM fisheries were simulated using either post-season estimates of exploitation rates (USAct), or with a $25 \%$ reduction in exploitation rates from the 1979 through 1982 base period (US25). Two exceptions existed to the latter case. For the WCVI net fishery, and for the Washington Coastal net fishery, post-season estimates of exploitation rates were used for both US-Act and US-25. The WCVI net fishery is managed primarily to meet escapement objectives for the Robertson Creek Hatchery stock (one component of the WCVI hatchery stock), and much of the Washington Coastal net fishery is managed with stepped harvest rates and an escapement floor. The CTC concluded that regimes in these fisheries were unlikely to be modified in a manner that would consistently reduce exploitation rates by $25 \%$ from the 1979 through 1982 base period.

### 2.1.2 Canadian Proposal

The Canadian proposal for AABM fisheries differs from the U.S. proposal in at least three fundamental ways:

1) the allowable fishery impacts are derived from a measure of abundance that is computed for fishery aggregates that span both nations rather than a fishery (or fishery aggregates) within a nation (Table 2);
2) the allowable fishery impacts are expressed in terms of total adult equivalent (AEQ) mortality rather than catch;
3) the HRI is a $50 \%$ reduction from the 1979 through 1982 base period rather than a stepped schedule in which the HRI is dependent on the AI.

The Canadian proposal does not specify the means to allocate the total allowable impacts between fisheries. Based upon recommendations of Canadian members of the CTC, $50 \%$ of the allowable impacts within the SEAK/NBC regional aggregate were allocated to SEAK, and 75\% of the allowable impacts within the WCVI/NLP regional aggregate were allocated to the WCVI troll fishery. Additional information regarding the allocation of allowable impacts between gear types is provided in Table 2.

Fisheries designated as ISBM in the Canadian proposal were simulated in the same manner as previously described for the U.S. proposal.

### 2.2 Modifications to PSC Chinook Model

Simulation of the proposed regimes required extensive modification of the PSC chinook model. While a detailed description of those modifications is beyond the scope of this report, we have provided a summary of the sequence of computations in the base model and in the enhanced version used in the simulation of the U.S. and Canadian proposals (Table 3).

Extensive revisions were required for the model computations for chinook nonretention (CNR) mortality. When retrospective assessments of abundance-based regimes are performed, usersupplied data on season length, effort, and encounters are no longer directly applicable since allowable catch levels change from historically observed levels. The AABM version of the PSC chinook model has incorporated new algorithms that adjust user-supplied data for differences in landed catch between the level allowed under AABM levels and observed actual catches. Revisions to the three general algorithms used by the CTC are described below.

RT Method. No change in the algorithm is required.
Reported Encounter Method. This method uses user-supplied estimates of legal-sized CNR encounters (LCNREnc), sublegal-sized CNR encounters (SubCNREnc), and landed catch (LC).

Step 1. Compute total potential legal encounters
PotLegEnc $=$ Potential Encounters (Real Fish) $=$ Observed Catch+Reported Legal CNR/Legal Selectivity Factor)
Step 2. Convert model catch (preterminal and terminal combined) under AABM regime to real fish (AdjMC) and estimate the number of legal sized encounters (LCNRABM)

LCNRABM $=(\text { PotLegEnc-AdjMC })^{*}$ Legal Selectivity Factor
Step 3. Adjust LCNREnc to model fish and estimate legal CNR mortality
Legal CNRMortality $=$ LCNREnc*(Release + Drop Off Mortality Rate for legal-sized fish)
Step 4. Estimate sublegal CNR encounters
Sublegal Encounters=LCNRABM* ${ }^{*}$ (SubCNREnc/LCNREnc)

Step 5. Estimate sublegal CNR mortality
Sublegal CNRMortality = Sublegal Encounters*(Release + Drop Off Mortality Rate for sublegal-sized fish)
Effort and Season Length Method. This method utilizes data on the number of days (or effort) of chinook retention and the number of days (or effort) of fishing under non-retention regulations.

Step 1. Compute new retention period in proportion to observed retention data

> New Retention = Observed Retention*(Estimated Fishery Catch/Observed Catch)

Step 2. Compute new nonretention data

$$
\text { New Non-Retention }=\text { MAX }\{0, \text { Observed Non-Retention }+(\text { Observed Retention-New Retention })\}
$$

For all CNR methods: 1) legal CNR mortality is distributed by stock and age in proportion to legal catch; and 2) sublegal CNR mortality is distributed among stock and age in proportion to fraction non-vulnerable, in the same manner as used to distribute other sublegal shaker mortality.

Table 1. Summary of parameters and computations used by the CTC to simulate the U.S. proposal for AABM fisheries.

| Region | Gear Type Used for Abundance Index | Catch HRI Schedule |  | Computation of Allowable Catch | Allocation of Catch |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SEAK | SEAK Troll | $\begin{aligned} & \mathrm{AI}<0.60 \\ & 0.60<\mathrm{AI}<1.18 \\ & 1.18<\mathrm{AI}<1.90 \\ & 1.90<\mathrm{AI} \\ & \hline \end{aligned}$ | $\begin{aligned} & \mathrm{HRI}=0.55 \\ & \mathrm{HRI}=0.60 \\ & \mathrm{HRI}=0.65 \\ & \mathrm{HRI}=0.70 \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { Troll Catch }=\mathrm{e}^{\left(12.38+\ln \left(\mathrm{HRI} \mathrm{I}^{*} \mathrm{AD}\right)\right.} \\ & \text { Total Catch }=20,000+(\text { Troll Catch }) / 0.80 \end{aligned}$ | $\begin{aligned} & \text { Net }=20,000 \\ & \text { Troll }=0.80^{*}(\text { Total Catch }-20,000) \\ & \text { Sport }=0.20^{*}(\text { Total Catch }-20,000) \end{aligned}$ |

### 3.0 Comparison of Regimes

The CTC has provided seven statistics to contrast the proposals and the benchmark model run: 1) abundance indices by fishery; 2) harvest rate indices by fishery; 3) non-ceiling fishery indices; 4) total catch by naturally-spawning stock and fishery; 5) total adult equivalent mortality by stock and fishery; 6) brood exploitation rates by stock; and 7) escapements by naturally spawning stock. For each statistic, we begin by describing what the statistic measures, suggestions for interpreting the statistic, and a brief summary of the results from the retrospective analysis.

Abundance Indices by Fishery. The model abundance estimates are based on biological information (e.g., productivity, escapement goals, age at maturity, catch distribution patterns, survival rates, enhancement levels) and estimates of fishing mortalities. An AI is computed by dividing the abundance in any year by the average abundance during the base period (1979 through 1982). We have provided AIs for the primary fisheries suggested for AABM in either the U.S. or Canadian proposals in Appendix A. Changes in AIs relative to the benchmark are summarized in Figure 1.

Figure 1. Average percent change in abundance indices by fishery relative to the benchmark.

Harvest Rate Indices by Fishery. The HRI is the ratio of stock and age-specific exploitation rates for total AEQ mortality in a fishery in a year relative to the 1979 through 1982 base period. An index less than 1.0 represents a decrease from base period harvest rates while an index greater than 1.0 represents an increase. We have provided HRIs for sport and troll fisheries suggested for AABM in either the U.S. or Canadian proposals and expressed them relative to the benchmark value (Appendix B). Changes in HRI relative to the benchmark are summarized in Figure 2.

Figure 2. Average percent change in harvest rate indices by fishery relative to the benchmark.

Non-Ceiling Fishery Indices. The non-ceiling index compares on a stock-by-stock and calendar year basis the expected AEQ mortalities (assuming base period exploitation rates and current abundance) with the observed AEQ mortalities over all the ISBM fisheries of a Party. Index values greater than 1.0 indicate that exploitation rates have increased relative to the 1979 through 1982 base period. A non-ceiling index is provided for each naturally spawning chinook stock included in the PSC chinook model, and the index is reported separately for U.S. and Canadian ISBM fisheries (Appendix C). Note that since the ISBM fisheries are not consistently defined in the U.S. and Canadian proposals, direct comparison of the index values is appropriate only within proposals(e.g., US-Act vs. US-25).

Total Catch by Stock and Fishery. The catch in a fishery results from the abundance of chinook salmon, the HRI applied, and the minimum size limits and/or other fishing regulations affecting incidental mortality. Catches are presented in Appendix D by fishery and stock, a sum for all stocks included in the model (Model Catch), and for all stocks contributing to the fishery (Total Catch). "Model Catch" may deviate from "Total Catch" if not all stocks contributing to the fishery are represented in the model, or if model biases result in predicted catches that deviate from the true values. Percent changes from benchmark values under the simulated regimes are presented for these periods (1985-1990; 1991-1996; 1985-1996); the 1985-1996 average change is presented in Figures 3-1 and 3-2.

Figure 3-1. Average percent change in catches relative to the benchmark over the 19851996 period of retrospective analysis, part 1.

Figure 3-2. Average percent change in catches relative to the benchmark over the 19851996 period of retrospective analysis, part 2.

Total AEQ Mortalities by Stock and Fishery. The AEQ mortalities in a fishery result from the abundance of chinook salmon, the harvest rate index applied, minimum size limits (and/or other fishing regulations affecting incidental mortality), and CNR. Percent changes from benchmark values under the simulated regimes are presented for three periods (1985-1990; 1991-1996; 1985-1996) in Appendix E. The 1985-1996 average changes in total AEQ mortality are summarized in Figure 4.

Figure 4. Average percent change in total adult equivalent mortalities relative to the benchmark.

Brood Exploitation Rates by Stock. Brood year exploitation rates provide the best measure of the cumulative impact of fisheries upon all age classes of a stock. The rates are computed as the ratio of AEQ mortality to AEQ mortality plus escapement. Brood year exploitation rates by model stock are presented for three time periods (1985-1990; 1991-1996; 1985-1996) in Appendix F. Changes in brood year exploitation rates for the 1985-1996 period are summarized in Figures 5-1 through 5-3.

Figure 5-1. Percent change in average brood year exploitation rates relative to the benchmark for Alaska and Canada stocks.

Figure 5-2. Percent change in average brood year exploitation rates relative to the benchmark for Puget Sound stocks.

Figure 5-3. Percent change in average brood year exploitation rates relative to the benchmark for other Washington and Oregon stocks.

Escapement by Stock. The escapement of a stock reflects the cumulative effect of all previous survival rates and fishery exploitation. The escapements reported in the benchmark column of tables in Appendix G are model predictions; deviations from observed escapements may occur due to random errors or biases in the model calibration.

Figure 6-1. Percent change in 1985-1996 average model-estimated escapements relative to the benchmark for Alaska and Canada stocks.

Figure 6-2. Percent change in 1985-1996 average model-estimated escapements relative to the benchmark for Puget Sound stocks.

Figure 6-3. Percent change in 1985-1996 average model-estimated escapements relative to the benchmark for other Washington and Oregon stocks.

### 4.0 Discussion

The CTC has provided a preliminary analysis of the U.S. and Canadian proposals for abundancebased regimes for chinook fisheries. The analysis should provide a useful basis for initiating discussions, but is limited by: 1) the scope and implementation of the retrospective analysis as identified in Section 1;2) the extent of the review by the CTC; 3) and the lack of agreed biologically-based escapement goals and exploitation rates against which to compare the proposals. The CTC is currently working to complete an assessment of the escapement goals and sustainable exploitation rates for naturally spawning chinook salmon stocks, and will update this report when that task has been completed. Adoption of new goals may alter the magnitude, but not necessarily the pattern, of deviations from the benchmarks. The CTC also will continue to review and improve the methods and data used in the analysis.

Appendix E. Total AEQ Mortalities by Stock and Fishery

## List of Tables

Table E-1. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Alaska Troll.

Table E-2. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Alaska Net \& Sport.

Table E-3. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - North Troll.

Table E-4. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Central Troll.

Table E-5. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - WCVI Troll.

Table E-6. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - WCVI Sport.

Table E-7. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Geo. St. Troll \& Sport.

Table E-8. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - WA/OR Troll.

Table E-9. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Other CAN.

Table E-10. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Other US.

Table E-11. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Total CAN.

Table E-12. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks - Total US.

Table E-1. Retrospective comparison of AEQ mortalities including catch, shakers, legal CNR, and sublegal CNR for model chinook stocks.
