1989 PROGRESS REPORT ON GENETIC STOCK IDENTIFICATION OF CHUM SALMON  
IN SOUTHERN BRITISH COLUMBIA AND WASHINGTON

### Introduction

In November of 1986, the Pacific Salmon Commission requested that the Joint Chum Technical Committee (CTC) provide estimates of stock composition in intercepting fisheries in southern British Columbia and Washington. The Commission identified the following components of that task:

- 1) Attempt to develop agreed-upon criteria and methods for the application of currently available genetic stock identification (GSI) data to catch data;
- 2) Evaluate and develop recommendations for standardization of GSI sampling, processing, and analysis methods;
- 3) Apply the above methodology to catch data for the fisheries for which adequate GSI data are available.

This report provides a synopsis of the current progress on these tasks. Earlier progress on these tasks has been reported by the CTC in TCCHUM 8702 and TCCHUM (88)-2. Current work has focused on the development of a baseline which provides accurate estimates of stock composition for each fishery. A subcommittee of the CTC has conducted analyses which compare several 7-loci baselines and their accuracy and precision. Based on this work, we make the following recommendations for the use of GSI for chum salmon stock composition estimates.

### Recommendations

The first recommendation is in the form of a general cautionary note regarding interpretation of GSI stock composition estimates.

1. Estimates of a particular stock contribution that comprise a small portion of a fishery (e.g. 10%) may be subject to a greater relative bias than estimates comprising a large portion of a fishery (e.g. 80%). However, estimates for stocks which comprise a small portion of the fishery generally have lower absolute biases than for stocks which comprise a larger portion of the fishery. The impact of this finding is illustrated in the following example:

Table 1. Relation between stock composition and relative and absolute bias in the estimate of the catch composition.

	Observed Catch	Stock True	Composition Estimated	True Catch	Estimated Catch	Rel. Bias	Abs. Bias
case 1	500,000	0.1%	5%	500	25,000	4900%	24,500
case 2	500,000	70.0%	80%	350,000	400,000	14%	50,000

The following recommendation concerns estimating stock compositions of intercepting fisheries sampled at the 7-loci level.

2. Use the baseline samples that produce the least biased estimates of stock composition, provided that acceptable levels of precision are maintained. A single baseline is not applicable to all fisheries. If a 7-loci baseline is used to estimate stock compositions in chum fisheries, a baseline with relatively few U.S. stocks is preferred for use in fisheries where the U.S. portion is expected to comprise 15% or less of the annual catch. These fisheries are Johnstone Strait, Georgia Strait, and Nitinat. In fisheries where the U.S. portion is expected to comprise 60% or more of the annual catch, a baseline with relatively equal numbers of U.S. and Canadian stocks provides the most accurate estimates. An example would be the Juan de Fuca net fishery. It is unclear what sort of baseline is suitable when estimating stock compositions in fisheries when U.S. stocks are expected to comprise between 15 and 60% of the annual catch.

Recommendations for estimating stock compositions from fisheries which are sampled at the 21-loci level are not yet provided.

3. The analyses comparing accuracy and precision of a 7-loci and 21-loci baselines need further refinement before conclusions can be made. At the end of 1988, baseline stocks analyzed for 21-loci were available for all U.S. stocks and a subset of southern Canadian stocks. The issue of whether a 21-loci data set will result in improved stock composition estimates will be investigated further during 1989, using the available baseline data.

Stock composition estimates can be provided at several different levels of detail, depending on management requirements, desired accuracy, and precision. As a minimum, a two way (e.g. U.S./Canada) split in stock composition estimates is required.

4. After the simulations in the third recommendation have been completed, the CTC will require further guidance on the desired level of stock grouping and the acceptable levels of bias and precision.

## Stock Composition Estimates

Stock composition estimates for Johnstone Strait, Georgia Strait, and Nitinat fisheries are presented for the years 1985 through 1987. Preliminary estimates for 1988 from these three fisheries will be available in Canadian agency reports. These estimates appear in Tables 1 through 13 in the Appendix. Final 1988 estimates will await further work on the comparison of 7-loci and 21-loci baselines. Catch composition estimates derived from these stock contribution estimates have yet to be developed by the CTC.

The stock composition estimates of the U.S. fisheries will not be presented until the outstanding issues regarding the use of 21-loci baselines are resolved. At that point, the CTC expects to present stock composition estimates from the Strait of Juan de Fuca fisheries from 1986-1988, and from the San Juan Island/Point Roberts fisheries from 1987 and 1988.

## Future Work

The Committee will be working on resolving the following outstanding GSI issues in 1989.

- Determining intra- and interannual variation in genetic characteristics of a stock, using baseline samples collected in 1987 and 1988 from the Nitinat hatchery as an example.
- Comparing the consistency of the laboratory procedures used in Washington and Canada by analyzing in each laboratory a set of identical samples from the Nitinat hatchery.
- Conducting simulations to determine the bias in the Nitinat baseline.
- Evaluating the changes in accuracy and precision of estimated stock compositions by using a 21-loci baselines instead of a 7-loci baseline as well as the implications in regards to sample size.
- Reaching agreement on methods for application of stock composition estimates to catch.
- Examining alternative methods of correcting for bias introduced by the selection of stocks in a baseline.
- Evaluating the effects that the utilization of genotypic versus allelic frequencies have upon the stock compositions.

- Evaluating the effects that the alternative estimation procedures used by Canada and Washington have upon the stock composition estimates.
- Investigating techniques other than electrophoretic analysis for stock identification and determining their utility for providing highly accurate and precise estimates of chum salmon stock composition.
