Tahltan Lake ..... 58
Tuya Lake ..... 58
Tatsamenie Lake ..... 58
Outplant Evaluation Surveys ..... 58
Acoustic and Trawl, Beach seine and Limnological Sampling ..... 58
In 1999, surveys continued to be directed by the Salmon Indexing Methods Unit of the StockAssessment Division of Fisheries and Oceans, Canada. Limnological beach seine surveyswere conducted at Tuya Lake by B. Mercer \& Associates Ltd.; acoustic and trawl surveyswere conducted at Tatsamenie, Tuya, and Tahltan lakes by B. Mercer \& Associates Ltd. Thelimnetic population estimates are based on the soundings and trawl samples only; beach seinecatches are not used. Currently, beach seine catches serve as a qualitative index of theabundance of fish in the littoral zone, which cannot be sampled by the acoustic and trawl gear.Density estimates are made from the sounding transects. Each lake is divided into a number oftransects and each transect is further divided into a number of depth strata. Limnetic fishpopulation (rounded to the nearest 100,000 ) and density estimates and beach seine catches arepresented in Table 8. Smolt Enumeration and Sampling58

Appendix E. 7. Klukshu River weir counts of Chinook, sockeye, and coho salmon, 1976-1999. ..... 143
Appendix E. 8. Alsek River sockeye salmon counts from U.S. and Canadian aerial surveys and from the electronic counter at Village Creek, 1985-1999. ..... 144
Appendix E. 9. Aerial survey index counts of Alsek Chinook salmon escapements, 1984-1999 ..... 145
Appendix E. 10. Aerial survey counts of coho salmon from U.S. lower Alsek River tributaries, 1984-1999 ..... 146

## LIST OF ACRONYMS

| ADF\&G | Alaska Department of Fish and Game |
| :--- | :--- |
| AF | Aboriginal Fishery |
| CAFN | Champagne Aishihik First Nation |
| CPUE | Catch per unit effort |
| CWT | Coded Wire Tag |
| DFO | Department of Fisheries and Oceans (Canada) |
| DIPAC | Douglas Island Pink and Chum (Private Hatchery) |
| ESSR | Excess Salmon to Spawning Requirement (surplus fishery license) |
| IHN | Infectious Hematopoietic Necrosis (a virus which infects sockeye salmon) |
| LCM | Latent Class Model |
| MEF | Mid-Eye-Fork (fish length measurement) |
| POH | Post-Obital-Hyperal (fish length measurement) |
| PSC | Pacific Salmon Commission |
| SMM | Stikine Management Model |
| SPA | Scale Pattern Analysis |
| TAC | Total Allowable Catch |
| TRTFN | Taku River Tlingit First Nation |
| TBR | Transboundary River |
| TTC | Transboundary Technical Committee |
| YSC | Yukon Salmon Committee |

## EXECUTIVE SUMMARY

Estimates of catches and escapements of Pacific salmon returning to the transboundary Stikine, Taku, and Alsek Rivers for 1999 are presented and compared with historical patterns. Relevant information pertaining to the management of appropriate U.S. and Canadian fisheries is presented and the use of inseason management models is discussed. Results from transboundary river sockeye salmon Oncorhynchus nerka enhancement projects are also reviewed.

## STIKINE

The 1999 Stikine sockeye salmon run is estimated at 124,600 fish, of which an estimated 106,000 fish were harvested in various fisheries including test fisheries, 400 fish were taken at the Tahltan Lake weir for otolith samples, and 2,900 Tahltan fish were used for broodstock. An estimated 16,800 Stikine fish escaped to spawn and 2,300 fish returned to the Tuya system and were not harvested. The catch was below average and the run below the 1989-1998 average run size and the lowest since 1990. Spawning escapements were also below goals. The estimated U.S. commercial catch of Stikine sockeye salmon in Districts 106 and 108 was 54,800 fish and the Canadian inriver commercial, aboriginal, and ESSR fishery catches were 33,100, 4,900, and 2,300 fish, respectively. A U.S. test fishery in District 108 harvested 3,900 Stikine sockeye salmon and the Canadian inriver test fishery catch included 5,900 sockeye salmon. The postseason estimate was close to the preseason forecast of 126,000 fish. The Stikine Management Model predicted a run greater than the preseason forecast after week 30. Weekly inseason model forecasts ranged from 76,000 to 227,000 sockeye salmon; the final inseason model prediction was 206,000 fish (both U.S. and Canada), with a total allowable catch (TAC) of 130,300 fish. Based on the inseason model estimates, both Parties harvested below their 50\% target of the TAC ( 65,000 Stikine sockeye salmon). However, postseason run estimate indicated that both countries exceeded their $50 \%$ portion of the TAC; Canada harvested $70 \%$ of the TAC and the U.S. harvested $101 \%$. The broodstock collection and otolith sampling removed 2,900 and 400 sockeye salmon, respectively; from the escapement to Tahltan Lake leaving a spawning escapement of 7,400 fish, falling below the goal of 24,000 fish through Tahltan weir. The estimated spawning escapement of 6,100 mainstem Stikine sockeye salmon was also below the objective of 20,000 to 40,000 fish for this stock group.

The catch of Chinook salmon O.tshawytscha in Canadian commercial and aboriginal fisheries in the Stikine River was 2,900 large fish and 1,300 jacks, $29 \%$ and $164 \%$ of the respective 19891998 averages. An additional 900 large and 100 jack Chinook salmon were taken in the Canadian inriver test fishery. The U.S. marine catch of Chinook salmon (all stocks) in the District 106 and 108 mixed stock gillnet fisheries was 1,600 fish, below the 1989-1998 average catch. The U.S. District 108 test fishery harvested 30 Chinook salmon. The Chinook salmon spawning escapement of 4,700 large adults through the Little Tahltan River weir in 1999 was 84\% of the 1989-1998 average

As with Chinook salmon, the U.S. marine harvest of Stikine coho salmon O. kisutch is unknown since there is no stock identification program for this species. Mixed stock coho salmon catches in Districts 106 and 108 were 203,300 and 28,000 fish, respectively, and were $2 \%$ and $70 \%$ above the 1989-1998 averages, respectively. Alaskan hatchery fish comprised approximately $39 \%$ ( 89,200 fish) of the coho salmon harvest from the two districts. The Canadian inriver coho salmon catch of 200 fish was 7\% of the 1989-1998 average.

## TAKU

The postseason estimate of the 1999 Taku sockeye salmon run is 183,800 fish, including an estimated catch of 85,700 fish and an above-border spawning escapement of 98,200 sockeye salmon. The run size and catches were about $75 \%$ of the 1989-1998 average while escapement was average and above the escapement goal range of 71,000 to 80,000 fish. An estimated 62,700 Taku sockeye salmon were harvested in the District 111 commercial fishery, $60 \%$ of the 19891998 average, and an estimated 1,300 sockeye salmon were harvested in the U.S. inriver personal use fishery. Canadian inriver commercial and aboriginal fishery catches included 20,700 and 400 sockeye salmon, respectively. The commercial catch was $76 \%$ of the 1989-1998 average, whereas the aboriginal catch was $87 \%$ above average. Since the escapement goal is expressed as a range, the resulting total allowable catch is also expressed as a range. In 1999, Canada harvested an estimated $31 \%$ to $34 \%$, and the U.S. took $48 \%$ to $52 \%$ of the total allowable catch.

The catch of large Chinook salmon in the Canadian commercial fishery in the Taku River was 900 fish, $53 \%$ of the 1989-1998 average; in addition, 260 jack Chinook salmon were caught compared to 1989-1998 averages of 1,700 and 200 fish, respectively. The Canadian aboriginal fishery in the Taku River harvested 50 large Chinook salmon. In the District 111 mixed stock gillnet fishery the catch of Chinook salmon was 1,800 fish, $55 \%$ of the 1989-1998 average. Approximately $27 \%$ of the catch, 500 fish, was estimated to be of Alaska hatchery origin. The escapement of 4,200 Chinook salmon counted in Taku River index areas was $36 \%$ of the 19891998 average and below the recently revised index escapement goal range of 5,800 to 10,500 fish.

The estimated above border run of Taku coho salmon in 1999 is 66,400 fish, which is $87 \%$ of the 1989-1998 average. The Canadian inriver commercial catch included 4,400 coho salmon, $80 \%$ of the 1988-1997 average. After upriver Canadian catches are subtracted from the inriver run, the above-border-spawning escapement is estimated at 61,000 coho salmon, which exceeds the minimum escapement goal of 38,000 fish. The U.S. harvest of 17,300 coho salmon in the District 111 mixed stock fishery was $21 \%$ of the 1989-1998 average. Alaskan hatcheries contributed an estimated $8 \%$ of the District 111 harvest, or 1,300 fish.

The harvest of 59,300 pink salmon O. gorbuscha in District 111 was $42 \%$ of the 1989-1998 average catch of 141,500 fish. Pink salmon were not retained in the Canadian commercial inriver fishery in 1999. The escapement of pink salmon to the Taku River was likely above average as evidenced by the fish wheel catch and release of 23,500 pink salmon, 49\% above the 1989-1998 average.
The catch of chum salmon $O$. keta in the District 111 fishery was 429,400 fish; composed of 424,600 summer run fish (prior to mid-August) and 4,800 fall run fish. The catch of summer chum salmon, primarily Alaskan hatchery stocks, was 227\% above the 1989-1998 average and was the highest on record. The catch of fall chum salmon, composed of wild Taku River and Port Snettisham stocks, was $36 \%$ of the 1989-1998 average. As with pink salmon, there was nonretention of chum salmon in the Canadian inriver fishery and the reported catch was 0 fish in 1999. Spawning escapement appeared to be poor; the Canyon Island fish wheel catch of 160 chum salmon was $35 \%$ of the 1989-1998 average and the second lowest on records dating back to 1984.

#### Abstract

Alsek The Alsek River sockeye salmon harvest of 11,400 fish in the U.S. commercial fishery was $58 \%$ of the 1989-1998 average. The Canadian inriver catch of 550 sockeye salmon was the second lowest on record, following 1997 and was 28\% of the 1989-1998 average. The aboriginal fishery harvested 550 sockeye salmon, $33 \%$ of the 1989-1998 average. No fish were harvested in the sport fishery. The low catches were the result of extensive closures in the sport and aboriginal fisheries due to conservation concerns. The Klukshu River weir count of 5,400 sockeye salmon was $31 \%$ of the 1989-1998 average and the lowest on record. The count of 400 early-run sockeye salmon (count through August 15) was $10 \%$ of the 1989-1998 average, whereas the count of 5,000 late run fish was $37 \%$ of average for the same period.

The Chinook salmon run to the Alsek River seemed average to below average. The U.S. Dry Bay catch of 500 Chinook salmon was $17 \%$ above the 1989-1998 average. The combined Canadian sport and aboriginal fishery catch of 430 Chinook salmon was $63 \%$ of the 1989-1998 average. The 2,200 Chinook salmon counted through the Klukshu River weir was $76 \%$ of the 1989-1998 average. Of the total count, 2,200 Chinook salmon were estimated to have spawned, thus achieving the escapement goal range of 1,100 to 2,300 Chinook salmon, established by the TTC for 1999. Aerial survey index counts of other spawning systems were average.

Current stock assessment programs are insufficient to provide accurate comparison of Alsek coho salmon runs with historical runs. The U.S. Dry Bay catch of 5,700 coho salmon was $98 \%$ of the 1989-1998 average, while the combined Canadian inriver aboriginal and sport fishery catch of 30 fish was $17 \%$ of the 1989-1998 average. The low catch was due to closures in the fisheries due to sockeye salmon conservation concerns. The operation of the Klukshu weir does not provide a complete enumeration of coho salmon into this system since it is removed before the run is over; however, it does provide a suitable annual index. The count of 2,600 coho salmon was 5\% above the 1989-1998 average.

## ENHANCEMENT

Eggs and milt were collected from the 1999 sockeye salmon escapements at Tahltan and Tatsamenie lakes. A total of 4,200,000 eggs were collected at Tahltan Lake, 70\% of the $6,000,000$ egg-take goal; the goal was not attained due to low escapement to the lake in 1999. At Tatsamenie Lake, approximately 500,000 eggs were taken which was $10 \%$ of the 5,000,000 egg target specified in the treaty. Additional eggs were not taken due to a shortfall in escapement.

Fry outplanted in June 1999 included 1,700,000 fry into Tahltan Lake, 1,600,000 fry of Tahltan Lake origin into Tuya Lake, and $1,800,000$ fry into Tatsamenie Lake; green-egg to planted fry survivals were $84 \%, 79 \%$, and $73 \%$, respectively. Survival to emergence was generally at, or below, expected levels; there were no losses to Infectious Hematopoietic Necrosis (IHN).

Outmigrant smolt sampling was conducted at Tahltan, Tuya, and Tatsamenie Lakes in 1999. Total emigration from Tahltan Lake was an estimated 762,000 smolts, less than the number expected. An estimated 294,000 smolts originated from the fry-planting program. Sampling at Tuya Lake was conducted to estimate age and size composition of the outmigrants but outmigration magnitude was not estimated. Sample size was limited due to logistics and timing. The Tatsamenie Lake mark-recapture program estimated that 776,000 smolts out-migrated from that system with planted fish contributing about 92,000 smolts.

The egg incubation and thermal-marking program was continued at Snettisham Hatchery in 1999. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Adult sockeye salmon otoliths were processed inseason by the ADF\&G otolith lab to estimate the weekly contribution of fish from U.S./Canada fry planting programs to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Preliminary contribution estimates of planted fish to Alaskan catches were 15,000 Stikine sockeye salmon to District 106 and 108 (11\% of catch) and 600 Taku sockeye salmon to District 111 ( $<1.0 \%$ of catch). Estimates of contributions to Canadian fisheries included 8,800 sockeye salmon ( $23 \%$ of catch) to Stikine River fisheries and 290 sockeye salmon to the Taku River fisheries ( $1.4 \%$ of catch).

## INTRODUCTION

This report presents estimates of the 1999 catch and escapement data for Pacific salmon runs to the transboundary Stikine, Taku, and Alsek Rivers and discusses management actions taken during the season. Catch and effort data are presented by management week (U.S. statistical week) for each river for both U.S. and Canadian fisheries. Spawning escapement data for most species are reported from weir counts or other escapement monitoring techniques. Joint enhancement activities on the Stikine and Taku rivers are also summarized.

The Transboundary Technical Committee (TTC) met prior to the season to update joint management, stock assessment and enhancement plans and determine forecasts for run strengths and initial TAC estimates for the various species and rivers. The results of this meeting are summarized in: Pacific Salmon Commission Transboundary Technical Committee. 1999. Salmon Management and Enhancement Plans for the Stikine, Taku and Alsek rivers, 1999. Report TCTR(99)-2.

Run reconstruction analyses are conducted on the sockeye salmon runs to the three rivers for the purpose of evaluating the stocks and the fisheries managed for these stocks. No estimates of marine catch are made for Alaskan fisheries outside of District 106 and 108 for Stikine stocks, District 111 for Taku stocks and Subdistrict 182-30 \& 31 for Alsek stocks.

## STIKINE RIVER

Stikine River salmon are harvested by U.S. gillnet fisheries in Alaskan Districts 106 and 108, by Canadian commercial gillnet fisheries located in the lower and upper Stikine River, and by a Canadian aboriginal fishery in the upper portion of the river. In addition, a Canadian terminal area fishery is operated in the lower Tuya River and/or at Tahltan Lake when escapements are estimated to be surplus to spawning requirements (ESSR) (Figure 1). A small sport fishery also exists in the Canadian sections of the Stikine drainage. In 1995, a United States personal use fishery was established in the lower Stikine River; no catches were reported in this fishery in 1995 through 1999. Additional catches of unknown quantity are taken in U.S. troll and seine fisheries and in sport fisheries near Wrangell and Petersburg. In 1996, the spring experimental troll area in the District 9 portion of Frederick Sound was expanded to target hatchery Chinook salmon; four previous areas were combined into one large area that also included previously unopened waters. This area was the same in 1999.

## Harvest Regulations and the Joint Management Model

Negotiations between Canada and the United States to replace expired portions of Annex IV, Chapter 1 of the Pacific Salmon Treaty resulted in the following arrangements for Stikine salmon which are expected to be in place for the 1999 to 2008 period

1. General:

The Parties shall improve procedures for coordinated or cooperative management of the fisheries on transboundary river stocks. To this end, the Parties affirm their intent to develop and implement abundance-based management regimes for transboundary Chinook, sockeye and coho salmon no later than May 1, 2004.follows:
2. Sockeye Salmon:
(i) Assessment of the annual run of Stikine River sockeye salmon shall be made as follows:
a. a pre-season forecast of the Stikine River sockeye salmon run will be made by the Committee prior to April 1 of each year. The Committee may modify the pre-season forecast prior to the opening of the fishing season;
b. in-season estimates of the Stikine River sockeye salmon run and the Total Allowable Catch (TAC) shall be made under the guidelines of an agreed Stikine Management Plan and using a forecast model developed by the Committee. Both U.S. and Canadian fishing patterns shall be based on current weekly estimates of the TAC. At the beginning of the season and up to an agreed date, the weekly estimates of the TAC shall be determined from the pre-season forecast of the run strength. After that date, the TAC shall be determined from the in-season forecast model;
c. modifications to the Stikine Management Plan and forecast model may be made prior to June 1 of each year by agreement of both Parties. Failure to reach agreement in modifications shall result in use of the model and parameters used in the previous year; and
d. estimates of the TAC may be adjusted in-season only by concurrence of both Parties' respective managers. Reasons for such adjustments must be provided to the Committee.
(ii) The Parties desire to maximize the harvest of planted Tahltan/Tuya sockeye salmon in their existing fisheries while considering the conservation needs of wild salmon runs. The Parties agree to manage the runs of Stikine River sockeye salmon to ensure that each country obtains $50 \%$ of the TAC in their existing fisheries. Canada will endeavor to harvest all fish surplus to escapement and broodstock needs returning to the Tuya and Tahltan Lake systems.
(iii) The Parties agree to continue the existing joint enhancement programs designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) Consistent with paragraph 1 above, the Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Stikine River. Assessment programs need to be further developed before a MSY escapement goal can be established.
(ii) In the interim, the United States' management intent is to ensure that sufficient coho salmon enter the Canadian section of the Stikine River to meet the agreed spawning objective, plus an annual Canadian catch of 4,000 coho salmon in a directed coho salmon fishery.
(3) Chinook salmon:
(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Stikine River are achieved.
(ii) The Parties agree that new fisheries on Stikine Chinook salmon will not be developed without the consent of both Parties. Consistent with paragraph 2, management of new directed fisheries will be abundance-based through an approach to be developed by the Committee. The Parties agree to implement assessment programs in support of the development of an abundance-based management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Stikine Chinook salmon by May 1999 and establish a new goal as soon as practicable thereafter.

As in most previous years, the Transboundary Technical Committee (TTC) met prior to the season to update joint management and enhancement plans, develop run forecasts and determine new parameters for input into the inseason run forecast model, referred to as the Stikine Management Model (SMM). The model was upgraded to provide inseason forecasts of the total Stikine sockeye salmon run as well as the following components of the run: the Tahltan stock (wild and planted combined); the Tuya enhanced stock; and the mainstem stocks. In addition, to address concerns raised as a result of the model over-estimating the run size in 1998, compensatory adjustments were made to the model for 1999. These included:

- reducing the CPUE values in the inriver commercial fishery by $25 \%$ since 1994 when the allowable gear for fishers was increased to two nets;
- re-calculating the regressions of weekly cumulative CPUE on total inriver run for those years in which the CPUE was adjusted downwards.
In 1999, the preseason forecasts were used during statistical week 26 (June 20 to June 26) through statistical week 27 (June 27 to July 03). After week 27, inseason forecasts of total run size and TAC, produced by the SMM and based on catch per unit effort (CPUE) data, were used to assist in determining weekly fishing plans (Table 1). The weekly inputs to the model included: the catch, effort and stock composition (proportion Tahltan/Tuya from egg diameters, proportion Tuya enhanced from thermal mark analyses of otoliths) in the Canadian lower river test and commercial fisheries; the upper river catch in the aboriginal fishery (AF) and upper river commercial fishery; the catch, effort and assumed stock composition in Subdistrict 106-41; and,
the catch and assumed stock composition in District 108 and Subdistrict 106-30. Results of thermal mark analyses were available inseason for the lower inriver fisheries to account for Tuya production in the model and reduce the risk of over-estimating the TAC of Tahltan sockeye salmon, which was expected to be below average in 1999.

Initially, average stock proportions in District 106 and 108 catches, from historical postseason scale pattern analysis (SPA), were assumed for weekly catches; the averages used each week depended upon

Postseason estimate (from Table 2).
124,614
${ }^{\text {a }}$ does not include ESSR or test fishery catches
whether the run was judged to be below average, average, or above average. The Tahltan/Tuya stock proportions were subsequently adjusted inseason based on the analysis of otolith samples taken in Districts 106 and 108. Inseason otolith sampling was conducted to estimate the contribution of planted Tahltan and Tuya Lake sockeye salmon to catches in these areas. The weekly estimate of Tuya fish in District 106-41 was added to the historical proportion of Tahltan fish in the SMM since this stock was not present in the historical database. No adjustments were
made in District 108. Because different proportions of Tahltan fish were observed in subdistricts of District 108, the overall contribution estimates for District 108 were weighted according to catches in the subdistricts.

The preseason forecast for the Stikine sockeye salmon run was 126,000 fish, which indicated a run size below the 1989-1998 average run of 197,284 fish (Appendix B.28). The forecast included approximately 61,000 natural Tahltan sockeye salmon (48\%), 3,000 planted Tahltan fish (2\%), 29,000 Tuya sockeye salmon (23\%), and 33,000 mainstem fish (26\%). Canadian inseason predictions of total run ranged from 75,890 to 227,182 sockeye salmon; U.S. forecasts ranged from 75,890 to 224,623 sockeye salmon (Table 1). All forecasts, other than the first week (week 28) indicated an above average run. The preseason forecast was more accurate than inseason forecasts in 1999. U.S. and Canadian weekly predictions differed only slightly this year; differences were due to different catch data input used for the updates.

## U.S. FISHERIES

The 1999 harvest in the District 106 commercial gillnet fishery included 518 Chinook, 104,878 sockeye, 203,262 coho, 490,716 pink, and 448,367 chum salmon (Appendix B.5). In the District 108 fishery, 1,049 Chinook, 36,548 sockeye, 28,437 coho, 48,550 pink and 117,196 chum salmon were harvested (Appendix B.7). District 106 catches of Chinook and sockeye salmon were $43 \%$ and $54 \%$ of the 1989-1998 respective averages while the coho salmon catch was average and the pink and chum salmon catches were above the average. The chum salmon catch was the largest on record (1960-1999) (Figure 2). The District 108 Chinook salmon catch was $78 \%$ of the 1989-1998 average and the sockeye salmon catch was $59 \%$ of average while the coho, pink and chum salmon catches were all above average. The coho salmon catch was $69 \%$ above average and the chum salmon catch was the highest on record. Weekly commercial and test fishery catches and stock composition estimates are provided in Appendices A.1-A.9. Annual commercial and test fishery catches from 1960 to 1999 for these fisheries are provided in Appendices B.1-B.11. Catches of each species in Districts 106 and 108 consist of fish of mixed stock origin; the contribution of Stikine stocks is estimated only for sockeye salmon. The proportion of the District 106 and 108 sockeye salmon catch of Stikine origin was estimated inseason using both the historical proportions of each stock and the thermally marked otoliths from runs of planted Tahltan and Tuya Lake sockeye salmon found in the catch.

The postseason estimate of the contribution of Stikine sockeye salmon to the District 106 and 108 catch is 48,901 or $34 \%$ of the total sockeye salmon catch of 141,426 fish. The Sumner Strait fishery (Subdistricts 106-41 \& 106-42) harvested 20,623 Stikine sockeye salmon (Appendix A.2), $28.1 \%$ of the total sockeye salmon harvest in that subdistrict, and the Clarence Strait fishery (Subdistrict 106-30) harvested 4,196 Stikine fish (Appendix A.4), 13.3\% of the total sockeye salmon catch in that subdistrict. The District 108 fishery harvested 29,980 Stikine sockeye salmon (Appendix A.8), 82\% of the District 108 sockeye salmon catch (Figure 3).

The Districts 106 and 108 fishing seasons began on June 20 (statistical week 26) and continued through October 12 (statistical week 42). This is the latest the fishery has been open since 1960. The initial opening in statistical week 26 was for two days in both districts. The initial opening in District 106 is normally two days and any decision to extend fishing is based on fishery catch rates estimated by management biologists on site in the fishery. The estimated sockeye salmon CPUE in both districts was above the 1989-1998 average for this week and the otolith analysis in the District 108 test fishery showed a Tuya:Tahltan ratio of approx. 50:50. Based on the catch
and otolith information and the preseason forecast of 64,000 Tahltan run, a 24 -hour extension was allowed in both districts to harvest the apparent surplus of Tahltan sockeye salmon. During statistical week 27 ( 27 June - 3 July) the fishery was open for two days. The sockeye salmon catch in District 8 was well above the 1989-1998 average but the catches in District 6 were below average. Based on the good sockeye salmon catches in District 108 and stock identification from the commercial and test fisheries which showed a high percent of Tahltan fish in District 108, District 106 was closed and an additional one-day mid-week opening was allowed in District 108. During statistical week 28 (4-10 July) Districts 106 and 108 were initially open for two days. The CPUE in District 108 (53 sockeye/boat/day) was above average while the District 106 CPUE of approximately 40 sockeye/boat/day was below average. The SMM also indicated that the Tahltan run was close to the preseason forecast and that the US catch of Tahltan fish was close to the TAC. Based on the Districts 106 and 108 sockeye salmon catches and the SMM results no extension or mid-week openings were warranted. During statistical week 29 (11-17 July) Districts 106 and 108 were open for two days. Sockeye salmon CPUE was good in the southern portion of
District 108, near the average in Clarence Strait and slightly below average in Sumner Strait. Although the SMM estimated the Tahltan run to be approximately 73,000 fish and the US TAC to be 24,000 the US biologists had doubts that the run was that large due to the poor catches in Frederick Sound portion of District 108. Therefore, no extensions or mid-week openings were warranted. During statistical week 30 ( $18-24$ July) Districts 106 and 108 were open for two days. Sockeye salmon CPUE in lower District 108, and in District 106 were all above average. The SMM along with the week 29 inriver catches indicated that the runs of all Stikine stocks were good and that the total US TAC was approximately 54,000. The current US catch of Stikine sockeye salmon was estimated at 24,000 so that approximately 30,000 Stikine sockeye salmon were still available for US harvest. Based on this information a $24-\mathrm{hr}$ extension in both districts was allowed and an additional 2-day mid-week opening was allowed in District 108. During statistical week 31 ( $25-31$ July) both districts were initially open for 3 days. The sockeye salmon CPUE for both districts was below average. However, due to the SMM showing the US TAC to be approximately 70,000 and that fish still remained for US harvest an additional 2-day mid-week opening in District 108 was allowed.

The test fishery that was initiated in District 108 during 1998 was undertaken again in 1999. Six gillnet vessels (three in Frederick Sound and three in the Sumner Strait portion of District 108) were contracted to fish for up to three days for three consecutive weeks from at specific locations of their choosing beginning on Tuesday, 15 June. However, due to very low catches during the first week an additional fourth fishing period was allowed so that additional samples needed for adequate statistical analysis could be obtained. Each of the vessels at each location fished different mesh sizes. The three sizes fished were: 4.625 in . to 4.875 in . ( 11.81 cm to 12.38 cm ); 5.375 in. to 5.25 in . ( 12.7 cm to 13.65 cm ); and 5.375 in . to 5.625 in . ( 13.65 cm to 14.29 cm ).

The objective of the fishery was to see if the Tuya sockeye salmon stock was more susceptible to capture in a particular gillnet mesh size than other stocks were. This is of interest because age 2.2 fish are very rare in the Tahltan stock while they may represent $25 \%$ or more of the Tuya marine

Figure 2. Average catches and fishing efforts compared with 1999 for the Alaska Districts 106 and 108 and for the Canadian inriver fisheries in the Stikine River.

Figure 3. Sockeye salmon catches for the Alaska Districts 106 and 108 and for the Canadian inriver fisheries in the Stikine River and Stikine River sockeye escapements, 1979-1999.
catch. Two-ocean age sockeye salmon are generally smaller than the 3-ocean fish and as such may be more susceptible to catch in smaller gillnets. If it could be shown that the Tahltan and Tuya stocks could be harvested at different rates then it may be possible to institute mesh size restrictions during years of low Tahltan runs to minimize the Tahltan stock catch while still fishing for the planted Tuya stock. Results after the first season did show a slight difference in the catch of age 2.2 sockeye salmon between mesh sizes with the smallest mesh size catching a higher percentage than either of the to other mesh sizes. A total of 3,936 sockeye salmon were caught during the test fishery. Planted Tahltan made up 3\%, Tuya made up $27 \%$ and wild stocks made up the remaining $70 \%$.

Area restrictions were used around the mouth of the Stikine River for the first two openings (statistical weeks 26 and 27) to protect adult Chinook salmon returning to the Stikine River. From 11 July through 28 July, the closure line for District 108 was moved in to the Point Rothsay to Indian Point line.

The management emphasis changed from sockeye to pink salmon during statistical week 32 (August 1 to 7). Pink salmon management normally begins near week 33 but the very large expected run of pink salmon to District 106 and the lack of Stikine sockeye salmon stocks in the week 31 catch prompted a slightly early directed pink salmon management efforts in both Districts 106 and 108. The District 106 catch is the ninth highest catch since 1960 and $14 \%$ above the 1989-1998 average of 429,405 pink salmon (Appendix B.5), while the District 108 catch is $30 \%$ above the average of 37,464 fish (Appendix B.7). Pink salmon catches in both districts are not always a true reflection of abundance because low pink salmon prices, along with a high abundance of sockeye salmon, affect the fishing patterns and methods. A three-day fishing period was allowed during statistical week 32. Four-day fishing periods were allowed for four consecutive weeks from statistical week 33 through statistical week 36 (8 Aug. - 4 Sept.).
Coho salmon management in both the District 106 and 108 gillnet fisheries usually commences during late August or early September. During statistical week 37 (5-11 Sept.) the management emphasis changed from pink to coho salmon. The coho salmon catches prior to week 37 had been slightly below the 1989-1998 average due to the late timing of the coho salmon run into inside waters. Three-day openings were allowed in both districts from week 37 through week 39 (5-22 Sept.) and two-day fisheries were allowed during weeks 40 through 42 (19 Sept. - 12 Oct.). The District 106 fishery was closed after week 42. Prior to the change to coho salmon management, the sockeye and pink salmon fisheries harvested 126,800 coho salmon, or approximately $63 \%$ of the total District 106 coho salmon catch.
During the 1999 season, the District 106 gillnet fishery was open for a total of 50 days (Appendix A.5), and the District 108 for 54 days (Appendix A.7). These were above the Districts 106 and 108 1989-1998 respective averages of 39 and 46 days. District 106 fishing effort in numbers of vessels was below the average for the first five openings, near or above the average for the next ten statistical weeks (weeks 32 to 41; 1 Aug. - 5 Oct.) (Appendix B.5). The number of vessels fishing in District 108 was near or above average for all openings. The greatest number of boat-days in District 106 (464) was in statistical week 36 while the greatest number of boats fishing (137) occurred in statistical week 31, which is the last week in July. The high number of boat-days fished during week 36 was due to the district being open for 4 consecutive days. The effort of 4,943 boat-days in District 106 was 20\% higher than the 1989-1998 average
of 4,092 boat-days. The 2,207 boat-days fished in District 108 was $67 \%$ higher than the 19891998 average of 1,323 boat-days (Appendix B.7). District 108 effort was higher than average due to the 4-day openings during weeks 33-36 and the large number of boats remaining in the district throughout the season.

## CANADIAN FISHERIES

Catches from the combined Canadian commercial and aboriginal gillnet fisheries in the Stikine River in 1999 included: 2,916 large Chinook, a record 1,264 jack Chinook, 38,055 sockeye, 181 coho, 11 pink, 8 chum salmon, and 14 steelhead salmon (Figure 4, Appendices A.10, A.12, A.13, B.17). In addition to these catches, 2,822 sockeye salmon were taken in an ESSR harvest in the Tuya River. Catches of all species except Chinook salmon were below average. The catch of large Chinook salmon was $29 \%$ above the 1989-1998 average of 2,263 and the catch of jack Chinook salmon was 2.6 times the average of 480 jacks. The sockeye salmon catch was approximately $9 \%$ below the average of 41,651 fish. Weekly commercial and test fishery catches and stock composition estimates for these fisheries are provided in Appendices A.10-A. 16 and annual catches from 1972 to 1999 are provided in Appendices B.12-B.21. The estimate of the total contribution of sockeye salmon from the Canada/U.S. fry-planting program to the combined Canadian aboriginal and commercial fisheries is 10,325 fish, $27.1 \%$ of the catch. Although the total catch of sockeye salmon was well within inseason limits established through the SMM, i.e. $42 \%$ below the final inseason target indicated by the SMM, it was approximately $21.6 \%$ above the postseason estimate of the allowable harvest for Canada (27,020 sockeye salmon) (Table 2). Catches of coho, pink, chum salmon, and steelhead salmon ranged from $3 \%$ to $10 \%$ of average (Appendix B.17).

A test fishery was conducted again in the lower Stikine River, just upstream from the Canada/U.S. border. Test fishery catches included: 853 large Chinook, 97 jack Chinook, 5,896 sockeye, 392 coho, 35 pink, and 29 chum salmon, and 43 steelhead trout (Appendix A.15). The test fishery was conducted only when the commercial fishery was closed and included ten drifts per day, five in the morning and five in the afternoon. The objectives of the test fishery during the sockeye salmon season were similar to those in previous years: to provide inseason catch, stock ID and effort data for input into the SMM to forecast the inriver run size; and, to determine migratory timing and stock composition of the sockeye salmon run for use in the postseason estimations of the inriver sockeye and coho salmon run sizes. As in 1998, the test fishery was expanded to test the feasibility of live-capturing coho salmon for the purposes of mark-recapture studies.

## Lower Stikine Commercial Fishery

Canadian commercial fishers in the lower Stikine harvested 2,127 large Chinook, a record 789 jack Chinook, 32,556 sockeye, 181 coho, 11 pink, and 8 chum salmon, and 14 steelhead trout in 1999 (Appendix A.10). The sockeye salmon catch was $92 \%$ of the 1989 to 1998 average of 35,342 fish (Appendix B.12). The catch of large Chinook salmon was $50 \%$ above the average of 1,414 large fish, and the jack Chinook salmon was 2.7 times average. Catches of coho, pink, and chum salmon ranged from $2 \%$ to $7 \%$ of average and the steelhead trout catch was $11 \%$ of the average of 126 fish.

Figure 3. Catches of Chinook, coho, pink, and chum salmon in the combined Canadian fisheries in the Stikine River, 1979-1999.

${ }^{a}$ Escapement into terminal and spawning areas from traditional fisheries.
${ }^{\mathrm{b}}$ Catch allowed in terminal areas under the Excess Salmon to Spawning Requirement license.
${ }^{\text {c }}$ Fish returning to the Tuya system are not able to access the lake where they originated due to velocity barriers.
${ }^{\mathrm{d}}$ The number of Tuya fish that should be pass through traditional fisheries in order to harvest the Tuya stock at the same rate as the Tahltan stock to ensure adequate spawning escapement for Tahltan fish.
${ }^{e}$ Includes traditional, ESSR, and test fishery catches.
${ }^{\mathrm{f}}$ Does not include ESSR or test fishery catches.
${ }^{\mathrm{g}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than in the listed fisheries.
Weekly guideline harvests, based on forecasts of the total allowable catch (TAC) apportioned by average run timing and domestic and international allocation agreements, were developed each week to guide management decisions during the sockeye salmon season. Management through statistical week 31 was focused primarily on the Tahltan sockeye salmon stock after which it
switched to mainstem sockeye salmon stocks through the end of August, and then to coho salmon. The Tahltan sockeye salmon stock was of particular concern given the preseason expectation of a below average run in 1999.
The fishery commenced at noon on Sunday, June 20 (statistical week 26) for a scheduled opening of two days. Fishing time was kept to 48 hours due to low numbers of sockeye salmon. Sockeye salmon catches increased the following week although the commercial sockeye salmon catch per unit of effort (CPUE) measured in sockeye/fisher/day (s/f/d) was below average as was the test fishery CPUE just prior to the opening in week 27. As a result, fishing time was kept to two days through week 27.

In statistical week 28, the fishery was scheduled to open for two days commencing Sunday, July 04. After the first 24 hours of fishing, the commercial sockeye salmon CPUE was $44 \%$ above average prompting a one day extension to the opening to bring the cumulative catch up closer to the weekly guideline harvest. The fishery closed after three days and the cumulative catch was approximately 700 fish below the guideline.

The peak sockeye salmon catch of the season, 10,815 fish, occurred in week 29. The fishery was open initially for 2 days but near a record sockeye salmon CPUE of $244 \mathrm{~s} / \mathrm{f} / \mathrm{d}$, which was $94 \%$ above average, and increases in the inriver forecast for the Tahltan run lead to the fishery being extended to four days. Based on SMM forecasts updated throughout the week, the guideline harvest of Tahltan sockeye salmon through week 29 was 21,000 to 24,000 fish, which was more than double the actual catch of Tahltan fish to this time. Because of the large apparent shortfall in catch, it was expected that a surplus of about 10,000 sockeye salmon would appear at Tahltan Lake.

Record high CPUE prevailed through week 30 and the SMM continued to indicate a growing surplus for Tahltan Lake as the commercial catch fell further behind the guideline harvest. The fishery was extended from the initial two day opening to five days as a result of the fishery performance. The extensions were granted for each 24 -hour period after the run assessment had been updated. After day 4 of this opening, the SMM indicated a shortfall in the cumulative lower river catch of approximately 11,000 to 23,000 Tahltan sockeye salmon. The overall sockeye salmon CPUE for this week was $203 \mathrm{~s} / \mathrm{f} / \mathrm{d}$, which was a record value for week 30, and was $64 \%$ above average. The CPUE of Tahltan sockeye salmon was more than four times the historic average for this week. Projections of the inriver run size of Tahltan sockeye salmon stock continued to indicate the cumulative catch of Tahltan fish in the lower river, estimated inseason to be approximately 16,000 fish through week 30 , was less than one half what it could have been.

The fishery in week 31 was opened for three days. The sockeye salmon CPUE dropped from above $200 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ in the previous week to $83 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ (slightly below average) and concern started to mount over the weir counts at Tahltan Lake, which were lagging behind expectations. Even though large shortfalls in the lower river catch were still indicated by the SMM, the fishery was not extended as a precautionary measure to ease up on the harvest of the Tahltan stock. The contribution of Tahltan sockeye salmon to the catch was approximately 54\% based on stock ID sampling; normally the contribution in this week would be closer to $25 \%$.

The contribution of mainstem sockeye salmon in the lower river catches predominated after week 31 (July 31 on) and the overall sockeye salmon CPUE values in the lower river were below average in weeks 32 and 33 . Fishing time remained at three days for the remainder of the
sockeye salmon season to harvest some of the surpluses of mainstem fish indicated by the SMM, although all three days were frequently not fished. Weekly catches after week 32 were well below average causing effort levels to drop 1- to- 3 fishers/week after week 33 (mid -August). Below average coho salmon catches provided little incentive for fishers to remain in the fishery after week 37 (September 11) which marked the end of the season.
Based on sockeye salmon CPUE in the lower river, the overall sockeye salmon run timing appeared to be compressed and approximately one week later than normal. The run peaked in week 29, one week later than the average peak in timing over the previous ten years. The Tahltan and Tuya stocks peaked in week 29; normally they peak over weeks 27 and 28 . Mainstem sockeye salmon peaked in week 32, roughly two weeks later than normal. Based on preliminary stock composition estimates, the lower river sockeye salmon catch was comprised of 18,046 wild Tahltan sockeye salmon ( $55 \%$ of the total catch), 7,862 planted Tuya fish ( $24 \%$ of the total catch), 5,952 mainstem sockeye salmon ( $18 \%$ of the total catch), and 696 planted Tahltan fish ( $2 \%$ of the total catch) (Table 2).

As a result of below goal escapement levels, there was no terminal harvest of sockeye salmon at Tahltan Lake in 1999 under an Excess Salmon to Spawning Requirements (ESSR) license. Instead, ESSR fishing activities again focused on the lower Tuya River to harvest fish returning from the fry-planting program. A total of 2,822 sockeye salmon was harvested in this area.
Twelve licensed fishers participated in the fishery throughout the season with a maximum of 11 licenses being active in any one week. The total effort in terms of boat-days was $261,65 \%$ of the 1989-1998 average of 400 boat-days. As in 1998, each fisher was allowed the use of two gillnets of which one could be a drift net. A maximum mesh size restriction of 150 mm through July 12 was implemented to reduce the incidental catch of Chinook salmon. In 1997, the upstream fishing boundary for the lower river fishery was moved approximately 25 km upstream to Flood River to increase the fishing area over previous years. The same area was fished in 1998 and in 1999.

## Upper Stikine Commercial Fishery

A small commercial fishery has existed near Telegraph Creek on the upper Stikine River since 1975. The catch recorded in 1999 included: 24 large Chinook salmon, which was $48 \%$ of the 1989-1998 average of 50 large fish; 12 Chinook jacks, $76 \%$ of average; and 625 sockeye salmon, which was $47 \%$ of average (Appendices A. 12 and B.14). The fishing effort was $50 \%$ of average with an average of only one fisher fishing two to five days per week. A total of 18 days was fished and the total effort amounted to 19 boat-days. For comparison, the 1989-1998 average fishing time was 24 days with an average effort of 38 boat-days.

## Aboriginal Fishery

The Stikine aboriginal fishery, which is located near Telegraph Creek, harvested 765 large Chinook, 463 jack Chinook, and 4,874 sockeye salmon (Appendix A 13). The catch of sockeye salmon was $98 \%$ of the 1989-1998 average of 4,982 fish. The harvest of large Chinook salmon was $96 \%$ of the average of 799 large fish while the jack Chinook salmon catch was the second highest on record and 2.7 times the average (Appendix B 15). As in past years, fishing times were not restricted in this fishery.

## EsCAPEMENT

## Sockeye

A total of 10,748 sockeye salmon was counted through the Tahltan Lake weir in 1999, $30 \%$ of the 1989-1998 average of 35,297 fish (Appendices A.17, B.22). An estimated 717 fish (7\%) originated from the fry-planting program, which was similar to the $7 \%$ of thermally marked fish observed in 1998. The estimate of planted fish in 1999 was based on the proportion of thermal marked Tahltan sockeye salmon as determined from otoliths from a random sampling of 429 fish collected at the weir. In addition, 2,870 sockeye salmon were collected for broodstock for the fry-planting project. This leaves a spawning escapement of 7,449 fish (Table 2). The weir count was below both the goal of 24,000 sockeye salmon and the goal range of 18,000 to 30,000 fish.

The spawning escapements for the mainstem and the Tuya stock groups are estimated indirectly by computing the ratio of Tahltan to mainstem and Tuya components in the total inriver sockeye salmon run. Stock identification data are collected in the lower river commercial and test fisheries. The ratios of Tahltan:mainstem and Tahltan:Tuya are applied to the estimated inriver Tahltan run size to develop an estimate of the total inriver sockeye salmon run. The escapements are estimated by subtracting the inriver catches from the inriver run estimate. The escapement estimates are 6,071 mainstem and 5,110 Tuya sockeye salmon. The mainstem sockeye salmon stocks spawn in tributaries and the mainstem of the Stikine River. The mainstem escapement is well below the escapement goal range of 20,000 to 40,000 fish. Aerial survey counts of sockeye salmon spawning the mainstem index areas totaled 651 fish compared to an average of 910 fish, not including Christina Creek and Craig River that were not surveyed in 1999 (Appendix B.23). The Tuya fish are blocked from entering potential spawning grounds of the Tuya tributary by natural barriers and are targeted in the ESSR fishery, which caught 2,822 fish in 1999 (Appendix B.18). The fate of the remaining 3,411 Tuya fish is unknown.

The Tahltan Lake sockeye salmon smolt outmigration was 762,033 fish in 1999 of which 293,545 originated from the fry planting program (Appendix A.18). This represents $76.7 \%$ of the 1984-1998 average of 993,410 smolt (Appendix B.24).

## Chinook

Chinook salmon escapement was enumerated at the Little Tahltan weir; 4,738 large fish and 202 jack Chinook salmon were counted between June 27 and August 12 (Appendix A.19, B.25). The escapement for large Chinook salmon was $93 \%$ of the old goal of 5,300 fish. The escapement goal for the Stikine River is currently being revised. Aerial surveys of the Tahltan River and Beatty Creek have been discontinued. The peak survey count at Andrew Creek was 605 large Chinook salmon, well within the escapement goal range of 325-750 fish. The aerial survey count for the Little Tahltan River was 1,379 fish, or $29 \%$ of the weir count (Appendix B.26, Figure 5). A mark-recapture study was conducted again in 1999. An escapement run size estimate is not available at the time of publication, but will be included in the final report.

## Coho

The aerial survey count of coho salmon at the index spawning areas is not yet available, historical counts are provided in Appendix B.27.

## Sockeye Run Reconstruction

The postseason estimate of the Stikine sockeye salmon run size is 124,614 fish, of which 59,349 are of Tahltan origin (wild \& planted), 31,382 are of Tuya origin (fry from Tahltan broodstock planted into Tuya Lake), and 33,884 are mainstem stocks (Table 2). These estimates are based on postseason SPA and otolith analysis in the U.S. Districts 106 and 108 catches and eggdiameter stock-composition estimates and otolith analysis for the Canadian commercial, aboriginal, ESSR, and test fishery catches; and escapement data. The 1999 total run is $63 \%$ of the 1989-1998 average run of 197,272 sockeye salmon but is close to the preseason forecast of 126,000 sockeye salmon.

Figure 4. Chinook salmon weir counts and index escapement estimates for major spawning areas and for the entire Stikine River, 1979-1999.

## TAKU RIVER

Taku River salmon are harvested in the U.S. gillnet fishery in the Alaskan District 111, in northern Southeast Alaska seine and troll fisheries, and in the Juneau area sport fishery and inriver personal use fishery (Figure 6). Canadian fisheries for Taku River salmon include a commercial gillnet fishery located in the river near the Canada/U.S. border, an aboriginal fishery, and a sport fishery.

## Harvest Regulations

New fishing arrangements were in place in 1999 as a result of negotiations between Canada and the United States of Annex IV, Chapter 1 of the Pacific Salmon Treaty. The arrangements that are expected to apply to the Taku River for the 1999 to 2008 period are as follows:
(1) Sockeye salmon:
(i) Except as noted below, Canada shall harvest no more than $18 \%$ of the TAC of the wild sockeye salmon originating in the Canadian portion of the Taku River each year;
(ii) If the projected above-border escapement is greater than 100,000 sockeye salmon, Canada may, in addition, harvest $20 \%$ of the projected escapement above 100,000 sockeye salmon;
(iii) The Parties agree to manage the runs of Taku River sockeye salmon to ensure that each country obtains catches in their existing fisheries equivalent to each country's share of wild sockeye salmon and a $50 \%$ share of fish originating from Taku fry plants;
(iv) The Parties agree to continue the existing joint Taku enhancement program designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) The Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Taku River no later than May 1, 2004. The Parties commit to developing a revised MSY escapement goal to be implemented no later than May 1, 2004.
(ii) Until a new abundance-based approach is developed, the management intent of the United States is to ensure a minimum above-border run of 38,000 coho salmon, and the following arrangements will apply:
a. no numerical limit on the Taku River coho salmon catch will apply in Canada during the directed sockeye salmon fishery (through statistical week 33);
b. if in-season projections of above-border run size are less than 50,000 coho salmon, a directed Canadian harvest of up to 3,000 coho salmon is allowed for assessment purposes as part of the joint Canada/US Taku River mark-recapture program;
c. if in-season projections of above-border run size exceed 50,000 coho salmon, a directed Canadian harvest of 5,000 coho salmon is allowed;
d. if in-season projections of above-border run size exceed 60,000 coho salmon, a directed Canadian harvest of 7,500 coho salmon is allowed;
e. if in-season projections of above border run size exceed 75,000 coho salmon, a directed Canadian harvest of 10,000 coho salmon is allowed.

## (3) Chinook salmon:

(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Taku River are achieved.
(ii) The Parties agree that new fisheries on Taku River Chinook salmon will not be developed without the consent of both Parties. Management of new directed fisheries will be abundance-based through an approach to be developed by the Committee no later than May 01, 2004. The Parties agree to implement assessment programs in support of the development of an abundance-based management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Taku River Chinook salmon by May 1999 and thereafter establish a new goal as soon as practicable.

## U.S. Fisheries

The 1999 commercial salmon harvests in the District 111 fishery totaled 1,841 Chinook, 79,425 sockeye, 17,273 coho, 59,316 pink, and 429,359 chum salmon (Figure 7). Catches of Chinook, sockeye, coho, and pink salmon were below average, but the catch of chum salmon was a record. Weekly commercial fishery catches and stock composition estimates for these fisheries are provided in Appendices C.1- C. 3 and annual catches from 1960 to 1998 are provided in Appendices D.1-D.3.
The Chinook salmon harvest of 1,841 fish was $55 \%$ of the 1989-1998 average of 3,356 fish (Appendix D.1). Alaskan hatchery fish contributed approximately $27 \%$ of the harvest or 499 fish as estimated by coded wire tag (CWT) analysis (Appendix C.1).

The sockeye salmon harvest of 79,425 fish was $67 \%$ of the 1989-1998 average catch of 119,042 fish (Appendix D.1, Figure 8). Weekly sockeye salmon catches were below average after the first week of the season, except for the SW36 catch of 2,314 fish, most of which (94\%) were domestic hatchery fish and local stocks taken inside Port Snettisham. The season catch was composed of the highest percentage (29\%) of age-1.2 sockeye salmon since data collecting began in 1982. The high incidence of the younger, smaller fish, which are not as susceptible to capture in gillnets as older, larger fish, is believed to have lowered the harvest rate for sockeye salmon in the fishery. The percentage of the harvest that occurred in Taku Inlet (Subdistrict 11132) was $87 \%$ of the total catch, near the 1988-1997 average of $83 \%$.

The contributions of Taku River and Port Snettisham sockeye salmon to the District 111 commercial drift gillnet harvest were 14,016 Kuthai, 20,843 Trapper, 18,680 mainstem, 9,791 Tatsamenie, 3,879 Crescent and 1,814 Speel fish. Sockeye salmon from joint U.S./Canada Taku River fry planting programs contributed an estimated 614 fish ( $<1 \%$ of the sockeye salmon catch), including 247 Trapper and 367 Tatsamenie fish. Contributions of domestic U.S. hatchery sockeye salmon to the District 111 gillnet fishery totaled 10,405 fish or $13 \%$ of the catch, and included a small number of thermally marked fish from a fry-planting program at Chilkat Lake in upper Lynn Canal.

Figure 5. The Taku River and principal U.S. and Canadian fishing areas.

The catch of 429,359 chum salmon was composed almost entirely (99\%) of summer chum salmon (Appendix D.1). The summer chum salmon run is considered to last through mid-August (SW33) and is composed of domestic hatchery and wild stocks. Chum salmon returning both to DIPAC hatcheries in Gastineau Channel and to the DIPAC remote release site at Limestone Inlet contributed a major portion of the catch but quantitative contribution estimates are not available. The summer chum salmon catch of 424,574 fish was the highest on record. As in recent years,
mesh size restrictions (minimum 6 inches) were employed during portions of the fishery openings in Section 11-B south of Circle Point (Subdistrict 111-31). This allowed harvest of hatchery chum salmon from the Limestone Inlet remote releases while limiting harvest rates on wild Snettisham sockeye salmon stocks.

The catch of 4,785 fall chum salmon (i.e., chum salmon caught after SW33) was $36 \%$ of the 1989-1998 average of 13,274 fish (Appendix D.1). Fall chum salmon caught in District 111 are wild fish from the Taku and Whiting Rivers.
The District 111 pink salmon harvest of 59,316 fish was $42 \%$ of the 1989 to 1998 average of 141,150 fish. Pink salmon were very small in size in 1999 and few were susceptible to harvest in the gillnet fishery. Runs of pink salmon to all streams in the district, including the Taku River, were very good; marine survivals for the 1997 brood year of pink salmon in Southeast Alaska were extraordinary. Approximately $74 \%$ of the District 111 pink salmon catch was made in Taku Inlet, and 26\% in Stephens Passage (Subdistricts 111-31 and 111-20).
Coho salmon stocks harvested in District 111 include runs to the Taku River, Port Snettisham, Stephens Passage, and local Juneau area streams as well as Alaska hatchery fish. The coho salmon catch of 17,273 fish was $21 \%$ of the 1989-1998 average of 82,196 fish (Appendix D.1). Coho salmon catches were well below average during each week of the summer fishing season. Coho salmon catches and CPUE remained below average during the fall fishing season as well. Alaskan hatchery coho salmon contributed 1,307 fish or $8 \%$ of the District 111 harvest, down significantly from previous years, although runs to local Alaska hatcheries were good to excellent (Appendix C.1). The local hatchery operator reported a significant reduction in the average weight of the 1999 adult coho salmon broodstock relative to previous years. Commercial fishers also reported encountering smaller sized fish in the fishery, which may have lowered the harvest rate for coho salmon in the fishery. The fall fishing season in District 111 lasted nine weeks, until October 13, the latest date this fishery has ever remained open. Three days of fishing time was allowed in Taku Inlet the first week of the fall season, and two days fishing each in the next four weeks (August 22 - September 18). This course of action was taken to conserve both Taku coho and fall chum salmon stocks. When the fall coho salmon markrecapture program indicated the escapement goal would likely be met, fishing time was increased to four days each in both SW39 and SW40, and three days fishing time each in SW41 and SW42.

The District 111 drift gillnet fishery was open for a total of 59 days from June 20 through October 13, 1999 (Figure 7). Fishing time was $25 \%$ above the 1989-1998 average. Fishing effort, as measured by the total number of boats delivering fish each week times the number of days open to fishing, totaled 2,841 boat-days, and was $80 \%$ of the 1989-1998 average. However, actual on the grounds fishing effort was less as the result of several factors. In weeks with five days of fishing time, many fishermen left the grounds early, not fishing the full five days. Also, there were two weeks in the summer fishery for which fishing effort was impacted from actions taken by a major fish buyer. Tenders stopped buying fish and left the grounds early on the morning of July 15 (SW29) because their plant had reached processing capacity. Additionally, strict catch limits for chum salmon were imposed on the majority of the fleet in statistical week 31. Both of these actions effectively limited fishing effort in those weeks.

Figure 6. Average catches and fishing efforts compared with 1999 values for the Alaska District 111 commercial fishery and the Canadian commercial fishery in the Taku River.

Figure 7. Sockeye salmon catches for the Alaska District 111, the Icy and Chatham Straits, the combined Canadian commercial and food fisheries in the Taku River, and Taku sockeye salmon escapement, 1979-1999.

Three days fishing time was allowed in Taku Inlet during each of the first two weeks of the season. The catch in the first week was above average, but fell below average in the following weeks. Fishing time was increased to four and five days per week in Taku Inlet during the period July 4-August 7 because mark-recapture estimates of inriver run size were increasing rapidly and a substantial U.S. TAC developed (Table 3). Fishing time during the final week of the summer fishing season (SW33: August 8-14) was limited to three days in order to increase passage of later-migrating Taku sockeye salmon stocks. Fishing time in Stephens Passage south of Circle Point (Subdistrict 111-31) was the same as in Taku Inlet (111-32) during the summer fishing season. Lower Stephens Passage (Subdistrict 111-20) was open to fishing for 10 days between August 8 and August 31 to allow harvest of surplus pink salmon.

Table 3. U.S. inseason forecasts of total run size, inriver run size, TAC, and U.S. harvest of Taku River sockeye salmon for 1999.

| Stat. | Total <br> Run | Inriver <br> Run | Total <br> TAC | U.S. <br> TAC $^{\text {a }}$ | Projected <br> U.S. |

${ }^{\text {a }}$ Inseason U.S. TAC calculated as $82 \%$ of the total TAC.

Port Snettisham was closed to fishing through August 28 to limit harvest rates on Crescent and Speel Lake wild sockeye salmon runs. Portions of Port Snettisham were opened each week beginning August 29. Although contributions of wild Snettisham sockeye salmon stocks to the harvest were unknown during the fishery, good escapements were apparent. A total of 10,277 sockeye salmon were counted through a weir DIPAC operated on the outlet stream to Speel Lake (Appendix D.10). The escapement to Crescent Lake was not enumerated through a weir, but a peak aerial survey count of 3,750 sockeye salmon and on-the-grounds observations during sampling trips indicated escapement was adequate and important spawning grounds appeared well seeded.

Several other fisheries in the Juneau area harvested transboundary Taku River stocks in 1999. Personal use permits were used to harvest Taku River fish with estimated catches of 22 Chinook, 1,254 sockeye, 44 coho, 105 pink, and 3 chum salmon (Appendix D.4). The spring Juneau-area sport fishery harvested an estimated 2,931 large Chinook (28 inches or longer) and 102 small Chinook salmon. Of the large fish, 2,161 (74\%) were wild mature, 46 (2\%) were wild immature and 724 (25\%) were hatchery fish (CWT estimate). A number of stocks are thought to contribute to the sport fishery, including those from the Taku, Chilkat, and King Salmon Rivers, and local hatchery stocks, but the major contributor of mature fish is believed to be the Taku River. The Hawk Inlet shoreline purse seine fishery north of Point Marsden in Chatham Strait was opened
for two days during July this year due to strong runs of early migrating pink salmon to the Juneau area. The fishery was open for 10 hours on July 18 and 15 hours on July 21, harvesting 597,700 pink, 46,400 chum, and 5,900 sockeye salmon. The fishery is limited to a harvest cap of 15,000 sockeye salmon during July.

## CANADIAN FISHERIES

Taku River commercial fishers harvested 908 large Chinook, 257 jack Chinook (fish less than 2.3 kg ), 20,681 sockeye, and 4,416 coho salmon, and 81 steelhead trout in 1999 (Appendix C.4). Catches of all species were below average. The sockeye salmon catch was $76 \%$ of the 1989-1998 average of 27,351 fish. Sockeye salmon originating from fry plants contributed 297 fish to the catch, comprising $1.4 \%$ of the total sockeye salmon harvest (Appendices C.5, C.6, D.6). The catch was comprised of an estimated 8,044 Kuthai, 6,485 Trapper, 2,992 Mainstem, and 3,160 Tatsamenie fish. The catch of coho salmon was $77 \%$ of the average of 5,748 fish. The catch of large Chinook salmon was $53 \%$ of the average of 1,721 large fish; however, the 257 jack Chinook salmon harvest was $28 \%$ above average (Appendix D.5). A total of 34 days was fished, $81 \%$ of the average of 42 days, and the seasonal fishing effort of 300 boat-days was $85 \%$ of the average of 354 boat-days. As in recent years, both set and drift gill netting techniques were utilized with the majority of the catch taken in drift gillnets. Mesh sizes were restricted to less than 150 mm through July 12 to minimize the incidental catch of Chinook salmon. In addition to the gillnets, one fish wheel was in operation.

In addition to the commercial catches, 50 Chinook and 382 sockeye and 471 coho salmon were harvested in the aboriginal fishery in 1999. The 1989-1998 average catches in the Taku aboriginal fishery have included 57 Chinook, 204 sockeye, 76 coho, 1 chum and 2 steelhead salmon (Appendix D.7). There was no creel census on the Nakina River in 1999

Two test fisheries were in operation in 1999: one, which operated late May through mid-June to sample for tagged Chinook salmon; and the other, which operated after week 37 (September 11) to sample for tagged coho salmon. Total test fishery catches included 577 large Chinook, 2 Chinook jacks, 88 sockeye, 688 coho, and 48 steelhead salmon (Appendix C. 7 and D.8).

The Canadian preseason forecast was for a run of approximately 202,900 sockeye salmon, which was the average of a sibling-based forecast of 158,700 sockeye salmon and a forecast of 247,000 fish based on stock-recruitment data. The point estimate was 17\% below the 1989-1998 average run size of approximately 245,600 sockeye salmon (Canadian estimate). The preseason forecast was used to guide weekly management actions for the first three weeks of the season; thereafter, inseason forecasts based on the joint Canada/U.S mark-recapture program at Canyon Island were used. For coho salmon, the preseason outlook was for a below average run due to anticipated below average marine survival.

The commercial fishery commenced at noon on Sunday, June 20 (statistical week 26) for a scheduled opening of two days. The commercial sockeye salmon CPUE was $52 \%$ below average and the fishery closed after 48 hours.
Over the next two weeks, i.e. weeks 27 and 28, the commercial fishery CPUE increased dramatically establishing weekly record values; the CPUE in week 28 (July 04-07) of 168 sockeye/fisher/day became the peak value of the 1999 season. Canyon Island fish wheel catches of sockeye salmon had also reached above average levels during the same time and the peak daily catch of the season occurred on July 05,235 sockeye salmon - a record high catch for this
date. The increased sockeye salmon abundance resulted in 24 hours extensions to the weekly commercial fishing periods in each of these weeks, which initially had opened for two days. The cumulative commercial catch through week 28 was 10,700 sockeye salmon, slightly above the inseason guideline harvest of 9,700 fish for this time (Table 4). Total escapement projections generated at the end of week 28 based on the joint Canada/US Taku mark-recapture program, ranged upward from 140,000 fish, well above the target of 71,000 to 80,000 sockeye salmon.

A precipitous decline in sockeye salmon abundance was noticeable in both the inriver commercial fishery and the Canyon Island fish wheels in week 29. The commercial sockeye salmon CPUE dropped to 31 sockeye/fisher/day, less than one third the 10-year weekly average value of approximately 97 sockeye/fisher/day, and the Canyon Island fish wheel catches remained well below long term daily averages for most of the week. In response, the fishery opening was kept to two days. The low inriver sockeye salmon catches resulted in a decrease in the escapement forecast, which dropped to approximately 116,000 fish and the total run forecast fell below 200,000 sockeye salmon (Table 4).

Table 4. Canadian inseason forecasts of total run size, total allowable catch (TAC), and spawning escapement of Taku sockeye salmon, 1999.

| Stat. <br> Week | Total Run | TAC | Escapement | Canada <br> TAC | Inseason <br> Guideline | Actual <br> Catch |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| 25 | 202,900 | 127,900 | 75,000 | 23,022 | 859 | 0 |
| 26 | 202,900 | 127,900 | 75,000 | 23,022 | 2,234 | 764 |
| 27 | 202,900 | 127,900 | 75,000 | 23,022 | 4,410 | 5,200 |
| 28 | 204,620 | 129,620 | 140,152 | 31,362 | 9,674 | 10,742 |
| 29 | 198,487 | 123,487 | 115,825 | 25,393 | 10,990 | 11,448 |
| 30 | 215,328 | 140,328 | 129,019 | 31,063 | 17,754 | 13,989 |
| 31 | 216,552 | 141,552 | 117,345 | 28,948 | 20,069 | 16,369 |
| 32 | 214,862 | 139,862 | 115,253 | 28,226 | 23,280 | 17,547 |
| 33 | 198,608 | 123,608 | 100,897 | 22,429 | 20,578 | 18,596 |
| 34 | 198,349 | 123,349 | 100,677 | 22,338 | 21,473 | 19,211 |

The fishery in week 30 was initially scheduled for 2 days. However, improved sockeye salmon catches at Canyon Island at the beginning of week 30 (July 18-24) and in the commercial fishery resulted in a 24 -hour extension. Over this period, the commercial sockeye salmon CPUE increased to approximately 75 sockeye/boat/day, but it was still $37 \%$ below average. After July 19, the daily fish wheel catches at Canyon Island slipped to below average values. However, run and escapement projections increased to 215,000 and 129,000 sockeye salmon, respectively (Table 4).
Fishing performance remained relatively unchanged in week 31 but noticeably declined thereafter. Forecasts of total run ranged from 216,600 fish in week 31 down to 198,300 fish in week 34, the final inseason projection. Escapement projections decreased from 117,300 fish in week 31 to 100,700 fish in week 34 . Through week 31, the cumulative commercial sockeye salmon catch was 16,400 fish compared to the inseason guideline of 20,100 sockeye salmon. Fishing time remained at 3 days per week through the end of August and despite decreased weekly fishing effort, fishing time was not increased to make up on the catch shortfall because of conservation concerns, particularly for Tatsamenie sockeye salmon stock. This concern arose
from the extended fishery in District 111, which was open for 5 days in each of weeks 31 and 32, at a time when historically, Tatsamenie stocks have been vulnerable in this fishery.

The cumulative commercial sockeye salmon CPUE over the season totaled 725 sockeye/fisher/day, $15 \%$ below the previous 10-year average of 854 sockeye/fisher/day. Run timing appeared to be normal in 1999 although it had an uncharacteristic early peak, which occurred over weeks 27 and 28. Normally the sockeye salmon run does not peak until week 30, the third week in July.
According to the postseason run estimate of approximately 183,885 sockeye salmon, the Canadian catch (excluding test fishery catches) of 21,063 fish represented approximately $19 \%$ to $20 \%$ of the TAC (Table 5).

After week 34, i.e. the third week in August, management attention shifted to coho salmon and to forecasts of the inriver run into Canada. Through week 35, the week ending August 28, the weekly CPUE in the commercial fishery was consistently below average and inriver run projections assuming the run was on time or one week late, ranged up to 47,000 coho salmon. According to the new harvest sharing arrangements, this meant that the Canadian quota after week 33 was 3,000 coho salmon. Heading into week 36 , it was anticipated the quota would be taken this week and this would be the last week of fishing for the season. The fishery in week 36 was extended to four days bringing the cumulative catch from week 34 through week 36 to 3,425 coho salmon. However, the run strength increased significantly in week 36 and the forecast increased to 54,000 fish by week's end. With the forecast in the 50-60,000 fish range, additional fishing was justified since the quota had jumped to the next level, i.e. 5,000 coho salmon.
A two-day opening was posted for week 37 but fishing effort consisted of only one fisher; other fishers had left immediately following the previous week's opening. The run forecast decreased in week 37 to below 50,000 coho salmon, which resulted in the closure of the fishery in week 38. Although subsequent inriver run forecasts increased after week 37 resulting in increased quotas, the fishery had been vacated and the logistics of fishers re-mobilizing and going back into the fishery were considered too onerous to be economical.

The total season coho salmon catch was 4,416 fish, $24 \%$ below the previous 10 -year average of 5,748 coho salmon and the cumulative coho salmon CPUE through week 37 was $19 \%$ above the previous 10 -year average. Run timing appeared to be one to two weeks late. The strength of the early part of the run, through week 35, appeared to be below average, whereas, after the end of August, run strength appeared to be above average.

## ESCAPEMENT

## Sockeye

Spawning escapement of sockeye salmon in the Canadian portion of the Taku River drainage is estimated from the joint Canada/U.S. mark-recapture program. Counting weirs operated by DFO at Little Trapper and Tatsamenie Lakes provide information on the distribution and abundance of discrete spawning stocks within the watershed. A sockeye salmon enumeration program was again conducted at Kuthai Lake by the TRTFN in 1999.

A mark-recapture program has been operated annually from 1984 to 1999 to estimate the aboveborder inriver run size (Appendices C.8, D.9). Spawning escapement is then estimated by subtracting the inriver catch. The 1999 estimate of border run is 119,304 sockeye salmon and the spawning escapement is estimated at 98,153 fish (Table 5). This spawning escapement is $96 \%$ of
the 1989-1998 average of 102,147 fish (Appendix D.9), and is above the interim escapement goal range of 71,000 to 80,000 sockeye salmon.

The escapement through the Little Trapper Lake weir was 11,805 sockeye salmon, $99 \%$ of the 1989-1998 average weir count of 11,888 fish (Appendices C.10, D.10).

Prior to 1995, weir counts for the Tatsamenie system were made at Little Tatsamenie Lake and included fish which spawn between Little Tatsamenie and Tatsamenie Lakes as well as fish which spawn in Tatsamenie Lake and its outlet stream. In 1995 the weir was moved upstream to Tatsamenie Lake. The escapement count through the Tatsamenie Lake weir in 1999 was 2,104 sockeye salmon (Appendices C9, D.10). To be comparable with earlier spawning estimates, it has been expanded to represent the entire Tatsamenie system. In 1994 weirs were operated at both Little Tatsamenie and Tatsamenie lakes; approximately $40 \%$ of the fish counted at the Little Tatsamenie weir did not migrate as far as the upper weir site at Tatsamenie Lake. Since this was from only one year and appears to be high, the upper Tatsamenie estimate was expanded by $1 / 0.8$ rather than $1 / 0.6$. The resulting escapement to the entire Tatsamenie system in 1999 is estimated at 2,630 fish. A total of 216 sockeye salmon was taken for broodstock leaving a spawning escapement of 1,888 sockeye salmon for 1999. The sockeye salmon count through the Kuthai Lake weir was 10,042 fish, the highest count on record and $247 \%$ of the 1992-1998 average count of 4,061 sockeye salmon (Appendices C. 11, D.10). The Nahlin weir was not operated in 1999.

## Chinook

Aerial surveys of large Chinook salmon (three-ocean and larger) to the six escapement index areas annually surveyed by ADF\&G were as follows: Nakina, 1,900 fish; Kowatua, 561 fish; Tatsatua, 431 fish; Dudidontu, 527 fish; Tseta, 221 fish; and Nahlin, 532 fish (Appendix D.11, Figure 9). The total of 4,172 large Chinook salmon observed was the lowest recorded since 1984 and was $36 \%$ of the 1989-1998 average. The expanded estimate of escapement of 20,545 fish is below the revised escapement goal range of 30,000 to 50,000 large Chinook salmon.

A Chinook salmon mark-recapture study was again conducted in 1999. The above-border run was estimated to be 28,045 fish. A test-fishery was conducted to complement spawning ground tag recovery data.
A carcass weir was again operated on the Nakina River to obtain tag and age-length-sex data on Chinook salmon (Appendix C.12). Only 180 Chinook salmon were observed at the weir - this represents the poorest carcass recovery on record. The Nahlin River weir was not installed in 1999 due to concerns that it impedes Chinook salmon migration.

## Coho

Spawning escapement of coho salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tag application and recovery occurred through the early part of statistical week 41 (October 3 to October 10). The aboveborder run was estimated to be 66,419 fish and the spawning escapement was estimated at 60,768 fish (Appendices C.8, D.12). The spawning escapement is $87 \%$ of the 1987-1998 average of 70,226 coho salmon; it exceeded the minimum escapement goal of 38,000 fish. Escapement

Figure 8. Taku River Chinook index escapement counts, 1975-1999.
counts to other Taku spawning locations were limited in 1999 with Yehring Creek above average and Fish Creek below average (Appendix D.13).

## Pink

There was no program in place to estimate the escapement of pink salmon to the Taku River in 1999. A total of 23,503 pink salmon was captured in the Canyon Island fish wheels in 1999 which is $49 \%$ above the 1989-1998 average of 15,768 fish (Appendix D.14).

## Chum

There was no program in place to estimate the system-wide escapement of chum salmon. Low catch and information from the Canyon Island fish wheels indicated that there was a below average chum salmon run in 1999. A total of 164 chum salmon was captured in the fish wheels, $35 \%$ of the 1989-1998 average of 463 fish and the second lowest on record (Appendix D.14).
The Taku River fall chum salmon run has continually declined since 1989. It is unlikely that the spawning escapement goal of 50,000 to 80,000 chum salmon was achieved.

## Steelhead

There was no program in place to estimate the system-wide steelhead salmon escapement. An escapement goal has not been set for this species.

## Sockeye Run Reconstruction

The postseason estimate of 62,713 wild Taku River sockeye salmon in the District 111 fishery (Table 5) was made from SPA and otolith analysis. The estimate of 247 planted Trapper Lake and 367 planted Tatsamenie Lake sockeye salmon the District 111 catch was based on expansion of otolith marked fish recovered in the District 111 fishery. The U.S. inriver personal use fishery harvested 1,254 sockeye salmon. The estimated total U.S. harvest of Taku River sockeye salmon is 64,581 fish (Table 5).

The estimate of the magnitude of the above-border sockeye salmon run in 1999, based on the joint Canada/U.S. mark-recapture program, was 119,304 fish. Subtracting the Canadian inriver catch of 21,063 sockeye salmon in the commercial, aboriginal and test fisheries, from the aboveborder run estimate results in an above-border escapement estimate of 98,153 fish.
The run size estimate, determined by summing the estimated U.S. District 111 and inriver harvest and the above-border run, was 183,885 sockeye salmon, which was $78 \%$ of the 19891998 average run size of 236,017 fish (Appendix D.9). Based on the escapement goal range of 71,000 to 80,000 fish, the TAC was 103,885 to 112,885 sockeye salmon, of which the U.S. harvested $57 \%$ to $62 \%$ and Canada harvested $19 \%$ to $20 \%$ (Table 5). The overall exploitation rate, not including test fishery catches was estimated to be $46 \%$ in 1999.

Table 5. Taku sockeye salmon run reconstruction, 1999. Estimates do not include spawning escapements below the U.S./Canada border.

## ALSEK RIVER

Alsek River salmon stocks contribute to the U.S. commercial gillnet fisheries located in Dry Bay, at the mouth of the Alsek River (Figure 10). Unknown quantities of Alsek origin fish are also taken in the U.S. commercial gillnet and troll fisheries in the Yakutat area. No commercial fishery exists in the Canadian portions of the Alsek River drainage, although aboriginal and recreational fisheries occur in the Tatshenshini River and some of its headwater tributaries (Figure 10).

## Harvest Regulations \& Management Objectives

Although catch sharing of Alsek salmon stocks between Canada and the U.S. has not yet been specified, Annex IV does call for the development and implementation of cooperative abundance-based management plans and programs for Alsek Chinook, sockeye and coho salmon. Interim escapement goal ranges for Alsek sockeye and coho salmon were initially set by the TTC at 33,000 to 58,000 sockeye salmon, and 5,400 to 25,000 coho salmon. However, stock assessment projects to determine system-wide escapements have not yet been developed. Instead, the principle escapement-monitoring tool for Chinook, sockeye, and coho salmon stocks on the Alsek River is the Klukshu weir, operated by DFO and the Champagne-Aishihik First Nation. The weir has been in operation since 1976. To make the management objectives of Chinook and sockeye salmon better defined in terms of Klukshu stocks, revised goals, expressed in terms of Klukshu stocks only, were tentatively established for 1999.

The initiative to establish a specific Klukshu Chinook spawning goal began in 1991 when the TTC set an interim spawning objective of 4,700 Klukshu Chinook salmon. This goal was based more on manager’s intuition than on science. From 1995 through 1997, the TTC reviewed this escapement level and concluded that goal of 4,700 Chinook salmon was not supported by the data. A new goal range of 1,100 to 2,300 fish was proposed based on joint analyses of stockrecruitment data. The Parties conducted independent internal reviews of the analyses. Although there was not unanimous support for the proposal, there was agreement on establishing a minimum goal consistent with the lower end of the proposed range. As a result, Canadian and U.S. managers agreed to a minimum spawning escapement goal of 1,100 Chinook salmon for the Klukshu system for the 1999 season.

The stock-recruitment analyses of Klukshu sockeye salmon data have not yet been completed nor has it undergone internal peer review. The analysis is following the same general methodology as was used for the Chinook salmon data. Analyses conducted by the TTC prior to the 1999 season resulted in establishing the following interim management objectives for 1999: a) a minimum escapement goal of 9,500 for the total Klukshu sockeye salmon run; and b) a minimum escapement goal of 1,500 for the early-run fish. These targets were to be considered interim only and subject to further revision upon completion of the analyses and peer review.

## Preseason Forecasts

The overall sockeye salmon run to the Klukshu River in 1999 was expected to be average in strength. The principal contributing brood years were 1994 (escapement of 13,892 sockeye salmon) and 1995 (escapement of 19,817 sockeye salmon); the 1989-98 average escapement was 16,356
fish. The range of escapements that appear most likely to produce maximum sustained yields is

Figure 9. The Alsek River and principal U.S. and Canadian fishing areas.

7,500 to 15,000 sockeye salmon based on historical stock-recruitment analyses. The 1999 overall Klukshu run was expected to be approximately 24,600 sockeye salmon based on the overall historical stock - recruitment relationship, similar to the 1989-1998 average (i.e., 24,600 fish). The early run escapements in 1994 and 1995 were 3,000 and 2,300 fish, respectively. Both years were above average and were close to the optimum level of 2,500 sockeye salmon spawners as determined through separate stock-recruitment analyses by DFO of the early run. Because of this, it was expected the early run component would be above average in strength. As a cautionary note, it was acknowledged the 1998 sockeye salmon run was much lower than expected, likely as a result of poor marine conditions. It was pointed out that it was reasonable to assume that these conditions could prevail and a similar run shortfall could occur in 1999.
The Klukshu Chinook salmon escapements in 1994 and 1995, 3,600 and 5,400 Chinook salmon, respectively, were above average with the 1995 escapement being the highest on record. However, the escapements were above the optimum escapement range of 1,100 to 2,300 fish as determined from current stock-recruitment analysis. As a result, the preliminary outlook was for a below average run.
The coho salmon escapements observed at the Klukshu River in 1995 (3,600 fish) and 1996 (3,500 fish) suggested the run in 1999 would be average to above average. The 1989-1998 average weir count for Klukshu coho salmon of 2,355 fish is an index count because unknown numbers of fish migrate up the Klukshu after the weir is dismantled for the season.

## U.S. FISHERIES

The Dry Bay commercial set gillnet fishery harvested 511 Chinook, 11,441 sockeye, 5,660 coho, and 112 chum salmon (Appendix E.1, Figure 11). The fishery was open for 44 days, $94 \%$ of the 1989-1998 average (Appendix E.4). The number of days actually fished, however, was only 37 because no fishing occurred after the Dry Bay buying station closed down in week 40. The majority of fishing time ( 28 days) occurred late in the season (late August through early October) after the sockeye salmon run had largely passed through the fishery. The total effort expended in the fishery was 330 boat-days, $67 \%$ of the 1989-1998 average. The estimate of subsistence harvests included 44 Chinook, 152 sockeye, and 21 coho salmon (Appendix E.5).

The Alsek River was opened to commercial fishing during statistical week 24, the first Monday in June (June 7). The initial opening was limited to 24 hours in order to evaluate Chinook and sockeye salmon run strengths. Fishery performance indicated that the sockeye salmon harvest was below expected levels and fishing time was not extended. CPUE continued below average during the next two weeks of the season (statistical weeks 25 and 26) and fishing time was again limited to 24 hours. Fishing time was increased to 72 hours during statistical week 27 because CPUE improved to well above average. During the following week CPUE dropped to just below average and fishing time was reduced to 48 hours. Fishing time was limited to 24 hours during each of the next four weeks due to below average CPUE. In

Figure 10. Average catches and fishing efforts compared with 1999 values for the Alaska Alsek River commercial fishery and the Canadian aboriginal and sport fisheries in the Alsek River.
early August, during statistical weeks 33 and 34 , fishing was limited to 48 hours in spite of CPUE levels two to three times average because Klukshu weir counts of sockeye salmon were below average.

The coho salmon harvest of 5,660 fish was 98\% of the 1989-1998 average. Escapement of coho salmon at the Klukshu weir was well above average early in the season and fishing periods ranged from 2 to 4 days during weeks 35 through 40 . No fishing occurred during the weeks 41 and 42 due to the closure of processing plant in Dry Bay.
Historically, a set gillnet fishery targeting on Chinook salmon was conducted during May and early-June. Due to depressed runs, the directed fishery has been closed since 1963 and Chinook salmon have only been harvested incidentally during the sockeye salmon fishery in early June. From 1963 through 1997, the early June periods were limited in time in order to reduce the impact on Chinook salmon. With the advent of the new Chinook salmon escapement goal concern for incidentally caught Chinook salmon has diminished so the management of the early June periods was based on sockeye salmon CPUE. Gillnet mesh size was restricted to a maximum of six inches through July 1. The Chinook salmon harvest of 511 fish was about $16 \%$ above the 1989-1998 average (Appendix E. 1 and E.4). Approximately 90\% of the Chinook salmon catch ( 459 fish), was taken during the first three weeks of the season.

The Alsek sockeye salmon harvest of 11,441 fish was $58 \%$ of the 1989-1998 average (Appendix E. 1 and E.4). The majority of the harvest ( $94 \%, 10,723$ fish) was taken in the river, with the remainder of the catch coming from the surf area. Adjustments to the weekly fishing periods during the sockeye salmon season relied heavily on fishery performance data; the decision of whether or not to extend any given period was initially based on catch and CPUE data gathered inseason during that particular period. From week 30 through 35, management was also based on Klukshu weir sockeye salmon counts. The Alsek management model was not used this year as a management tool because of unreliable run estimates produced in recent years.

## CANADIAN FISHERIES

The aboriginal fishery harvested an estimated 238 Chinook and 554 sockeye salmon. The catch of Chinook salmon was $81 \%$ of the 1989-1998 average of 295 fish. The sockeye salmon catch was the second lowest on record and was $33 \%$ of the average of 1,697 fish. Weekly catches and annual comparisons appear in Appendices E. 2 and E.6.

Catches in the recreational fishery were also well below average with an estimated 136 Chinook, 1 sockeye, and 20 coho salmon being harvested. Compared to the previous 10 -year averages, the Chinook salmon catch was $35 \%$ of average, the sockeye salmon catch was the lowest on record and was $0.4 \%$ of average, and the coho salmon catch was $14 \%$ of average. The low catches were attributed to extensive closures that were implemented due to conservation concerns for sockeye salmon. The catch data was derived from a creel census program conducted in the Dalton Post area by the Klukshu weir personnel. Weekly estimates and annual comparisons are listed in Appendices E.2, E.6.

Management of salmon in the Yukon is a shared responsibility between Fisheries and Oceans Canada (DFO) and the Yukon Salmon Committee (YSC). The YSC was established in 1995 pursuant to the Comprehensive Land Claim Umbrella Final Agreement between the Government of Canada, the Council for Yukon Indians and the Government of the Yukon. The Committee is
a public board consisting of ten members, $70 \%$ of which are appointed by Yukon First Nations. Two Champagne-Aishihik First Nation (CAFN) members sit on the YSC. Although the Committee currently operates by consensus, the voting
structure of the Committee is organized so that, should a vote be necessary, $50 \%$ of the votes reside with appointees of Yukon First Nations.

The 1999 Alsek-Tatshenshini management plan, adopted by CAFN, YSC, and DFO, was based on the objectives described in the Harvest Regulations \& Management Objectives section above. For Chinook and early sockeye salmon management, the status of the Klukshu weir counts was to be reviewed on or about July 15 to ensure weir and spawning escapement targets were on track. The status of the late sockeye salmon run would be reviewed at the end of August. Adjustments to inseason fishing regimes in the sport and aboriginal fisheries would be made if deemed necessary. Other key elements of the plan are described below.
The center of aboriginal fishing activity in the Alsek drainage occurs at the Champagne/Aishihik First Nation village of Klukshu, on the Haines road, about 60 km south of Haines Junction. Salmon are harvested by means of gaff and traditional fish traps as the fish migrate up the Klukshu River into Klukshu Lake. The fishing plan for the aboriginal fishery in the Klukshu River for the period prior to August 15 allowed fishing by means of fish traps for 2 days per week. After August 15, it was planned that the traps would be fished 3 days per week. Conservation thresholds that might invoke restrictions in the Aboriginal fishery were projected Klukshu weir counts of $<1,100$ Chinook and $<1,500$ early sockeye salmon. Gaff fisheries also exist on Village Creek and in the headwaters of the Tatshenshini River and tributaries thereof (Goat Creek, Stanley Creek, Parton River, and the Blanchard River). The plan did not restrict the gaff fishery other than to reserve Goat Creek, Stanley Creek, and the Parton River for elders only.
The majority of the sport fishing effort on this drainage occurs on the Tatshenshini River, at and just downstream of the mouth of the Klukshu River in the vicinity of the abandoned settlement of Dalton Post. The management plan prohibited the retention of sockeye salmon in the recreational fishery prior to August 15 unless the weir count projection for the early run was $>4,500$ sockeye salmon. The Chinook salmon daily catch limit was one fish and the possession limit was 2 Chinook salmon. For other salmon species, the daily catch and possession limits were 2, and 4, respectively. However, the aggregate limit for all salmon combined was 2 salmon per daily, 4 in possession. Sport fishing in the Dalton Post area was initially to be open from 6:00 am Saturday to 12:00 noon Tuesday each week. Headwater areas upstream of the British Columbia/Yukon border were to be closed for the season to protect spawning Chinook salmon. Conservation thresholds that were expected to invoke additional restrictions in the sport fishery were projected Klukshu weir counts of $<1,500$ Chinook and $<9,500$ sockeye salmon (early and late runs combined).
In 1999, the Yukon Salmon Committee introduced a mandatory Yukon Salmon Conservation Catch Card in an attempt to improve harvest estimates and to serve as a statistical base to ascertain the importance of salmon to the Yukon sport fishery. Anglers are required to report their catch via mail by the late fall. Information requested includes: the number, sex, size, date and location of salmon caught and released.
Stock status reviews conducted mid-late July raised conservation concerns for sockeye salmon when projections, based on weir counts to date and historic timing data, suggested that the weir
objectives for sockeye salmon were not likely to be achieved. As a result of these concerns, the non-retention for sockeye salmon in the sport fishery was extended, initially through September 30, and eventually through the entire fishing season. When it appeared the late run was also going to be weak, the sport fishery was closed to all fishing in the Klukshu River and in the Tatshenshini River downstream from the Klukshu River from September 04 through October 20. This action was taken to provide free access to the Klukshu for any remaining sockeye salmon. After October 20, the Klukshu River remained closed, whereas the Tatshenshini was opened to allow an opportunity to fish coho salmon, which appeared to be average to above average in abundance.

CAFN also imposed significant closures in the aboriginal fishery. On September 10 through October 15, fishing in the lower Klukshu River downstream of the weir was closed and the trap fishery near the outlet of Klukshu Lake was also closed. For the third consecutive year, depleted runs and closures in the aboriginal fishery seriously impacted CAFN fishers, resulting in basic needs levels not being achieved.

## EsCAPEMENT

It is currently not possible to accurately assess whether the system-wide escapement goals for Alsek Chinook, sockeye, and coho salmon are being met because total drainage enumeration programs are not established. A large, but unknown, and presumably variable proportion of the escapement of each species is enumerated at the weir on the Klukshu River (Appendices E.3, E.7, Figures 12-14). Current escapement monitoring programs including the Klukshu weir, Village Creek electronic counter, and aerial surveys do, however, allow annual comparisons of escapement indices (Appendices E.8-E.10). The most reliable comparative escapement index for Alsek drainage salmon stocks is the Klukshu River weir count. Escapements for 1999 are given in Table 5.

## Sockeye

The weir count and escapement of Klukshu River sockeye salmon was 5,381 and 5,010 fish respectively in 1999 (5), and consisted of a below average (1989-1998) count of 371 early-run fish (count through August 15) and a below average count (1989-1998) of 5,010 late-run sockeye salmon. The early-run count was $10 \%$ of the average of 3,755 fish, and the late-run count was $37 \%$ of the average of 13,661 sockeye salmon (Appendix E.7). Due to major equipment failure with the Village Creek electronic counter, a sockeye salmon escapement estimate is not available in 1999 (Appendix E.8).
Comparative counts for other Alsek index tributaries appear in Appendix E.8. A count of 30 sockeye salmon for Basin Creek was $2 \%$ of the 1989-1998 average of 1,284 fish, while the count of 800 sockeye salmon in the Tanis River was average compared to 831 fish.

## Chinook

The most reliable comparative Chinook salmon escapement index for the Alsek drainage is the Klukshu weir count. The Chinook salmon weir and escapement counts in 1999 were 2,193 and 2,168 fish respectively (Table 5), and were a respective $76 \%$ and $79 \%$ of average (Figure 13, Appendix E.7). The 1999 count achieved the escapement goal range of 1,100 to 2,300 Klukshu Chinook salmon.

Aerial Chinook salmon surveys were again flown in 1999. The count of 194 Chinook salmon in the Takhanne River was $90 \%$ of the 1989-1998 average of 216 fish. The Blanchard River and Goat Creek counts of 371 and 51 fish were $94 \%$ and $30 \%$ above their respective averages (Appendix E.9).

## Coho

The preliminary Klukshu weir count and escapements of 2,481 and 2,531 coho salmon were 5\% above and $3 \%$ below their respective averages of 2,355 and 2,617 fish (Table 5, Appendix E.7, Figure 14). The weir is removed prior to the completion of the coho salmon run and does not include fish that migrate after mid-October.

## Run Reconstruction

Estimates of the Klukshu contribution to the sockeye salmon run to the Alsek drainage vary from $37 \%$, as estimated from an ADF\&G mark-recapture study in 1983, to $60 \%$, based on Canadian fishery managers' professional judgment. The Klukshu weir count divided by the estimated proportion of Klukshu fish that constitute the total Alsek run, minus the recreational and aboriginal fishery catches yields an escapement estimate for the Alsek River. The estimated escapement added to the U.S. commercial and subsistence catches yields an estimate of the entire Alsek run. Using the $37 \%$ to $60 \%$ contribution range, the estimated sockeye salmon escapement in the Alsek River was on the order of 22,600 (Canada) to 36,700 (U.S.) fish and the estimated Alsek sockeye salmon run was on the order of 38,200 (Canada) to 52,300 (U.S.) sockeye salmon. The sockeye salmon escapement estimate falls at the lower range or below the sockeye salmon escapement goal range of from 33,000 (U.S.) to 58,000 (Canada) for the Alsek River.

Figure 11. Alsek sockeye catches and weir counts, 1979-1999.

Figure 12. Alsek Chinook catches and weir counts, 1979-1999.

Figure 13. Alsek coho catches and weir counts, 1979-1999.

Table 6. Catch and Klukshu index escapement data for Alsek sockeye, Chinook, and coho salmon for 1999.

|  | Sockeye | Chinook | Coho |
| :--- | ---: | ---: | ---: |
| Escapement Index $^{\text {a }}$ |  |  |  |
| Klukshu Weir Count | 5,381 | 2,193 | 2,481 |
| Klukshu Escapement | 5,101 | 2,168 | 2,531 |
|  |  |  |  |
| Harvest $^{\mathrm{b}}$ |  |  |  |
| U.S. Commercial $^{\text {U.S. Subsistence }}$ | 11,441 | 511 | 5,660 |
| Canadian Sport | 152 | 44 | 21 |
| Canadian Aboriginal | 0 | 192 | 28 |
| Total | 554 | 238 | 0 |
|  | 12,147 | 985 | 5,709 |

${ }^{a}$ Klukshu River salmon stocks represent an assumed large and variable portion of the total Alsek River salmon escapement.
${ }^{\mathrm{b}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for for catches other than the listed fisheries.

## ENHANCEMENT ACTIVITIES

## EgG COLLECTION

In 1999, sockeye salmon eggs were collected at Tahltan Lake on the Stikine River for the eleventh year, and in the Tatsamenie Lake system on the Taku River, for the tenth year. No eggs have been collected at Little Trapper Lake on the Taku River since 1994.

## Tahltan Lake: Target 6.0 million eggs

The egg collection was contracted to Arc Environmental Ltd. for the fourth consecutive year. Lower than average escapement in 1999 made capture of broodstock relatively difficult in comparison with previous years that had higher escapement levels. An estimated 4,180,000 eggs was collected from 1,442 females (based on an average historical fecundity of 2,900 eggs per female). A similar number of males were taken. The broodstock was collected by beach seine at the major spawning site as has been done in previous years.

## Tatsamenie Lake: Target 5.0 million eggs

Egg collection was again contracted to B. Mercer and Associates Ltd. An estimated 496,370 eggs were collected from 116 females (based on a measured fecundity of 4,241 eggs per female). Female sockeye salmon collected for a final egg take were lost when a bear tore a hole in the net pen. A total of 96 males were spawned. The low escapement in 1999 limited the availability of broodstock. The broodstock was captured at an adult enumeration weir that was located at the outlet of Tatsamenie Lake. This was the sixth year that all of the Tatsamenie broodstock was captured at this location. A total of 398 males and 299 females were held prior to September 20. Sixteen females and 159 males were released to ensure the broodstock did not exceed $30 \%$ of the escapement.

## Incubation and Fry Plants (1998 Brood Year)

Incubation of 1998 brood eggs took place at Snettisham Hatchery and the resultant fry were transported to the appropriate systems from May 29 to July 2, 1999. The IHN virus was not detected during the incubation period for the Tahltan and Tatsamenie fry.

## Tahltan Lake

An estimated 1,70,000 fry from the 1998 Tahltan sockeye salmon egg take were planted back into Tahltan Lake in 1999 (Table 7). Survival from green-egg to outplanted-fry was $84 \%$. Fry outplanting took place from May 29 through June 2.

## Tuya Lake

An estimated $1,600,000$ fry from the 1998 Tahltan sockeye salmon egg take were planted into Tuya Lake in 1999 (Table 7). Survival from green-egg to outplanted-fry was $79.2 \%$. Fry outplanting took place from June 21 to July 2.
Tatsamenie Lake
An estimated 1,800,000 fry from the 1998 egg-take were planted into Tatsamenie Lake in 1999 (Table 7). Survival from green-egg to outplanted-fry was $73.3 \%$. Outplanting took place from June 1 through June 9.

Table 7. Summary of sockeye salmon fry releases into Transboundary River Lake systems.

|  | Fry Destination |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
| Brood | Tahltan | Tuya | Trapper | Tatsamenie |
| 1989 | $1,042,000$ | 0 | 0 | 0 |
| 1990 | $3,600,000$ | 0 | 934,000 | 673,000 |
| 1991 | $1,400,000$ | $1,600,000$ | $1,800,000$ | $1,200,000$ |
| 1992 | $1,900,000$ | $2,000,000$ | $1,100,000$ | 909,000 |
| 1993 | 904,000 | $4,700,000$ | 916,000 | 521,000 |
| 1994 | $1,100,000$ | $2,300,000$ | 773,000 | 898,000 |
| 1995 | $2,300,000$ | $2,500,000$ | 0 | $1,700,000$ |
| 1996 | $2,200,000$ | $2,600,000$ | 0 | $3,900,000$ |
| 1997 | $1,900,000$ | 433,000 | 0 | $3,597,000$ |
| 1998 | $1,670,000$ | $1,603,000$ | 0 | $1,769,000$ |

## Outplant Evaluation Surveys

Acoustic and Trawl, Beach seine and Limnological Sampling
In 1999, surveys continued to be directed by the Salmon Indexing Methods Unit of the Stock Assessment Division of Fisheries and Oceans, Canada. Limnological beach seine surveys were conducted at Tuya Lake by B. Mercer \& Associates Ltd.; acoustic and trawl surveys were conducted at Tatsamenie, Tuya, and Tahltan lakes by B. Mercer \& Associates Ltd. The limnetic population estimates are based on the soundings and trawl samples only; beach seine catches are not used. Currently, beach seine catches serve as a qualitative index of the abundance of fish in the littoral zone, which cannot be sampled by the acoustic and trawl gear. Density estimates are
made from the sounding transects. Each lake is divided into a number of transects and each transect is further divided into a number of depth strata. Limnetic fish population (rounded to the nearest 100,000 ) and density estimates and beach seine catches are presented in Table 8 . Smolt Enumeration and Sampling

Smolt sampling and enumeration programs were conducted at Tahltan and Tatsamenie lakes. Only sampling was conducted at Tuya Lake. Sampling and enumeration at Tahltan Lake was conducted by DFO, Whitehorse, as part of the continuing smolt program. B. Mercer and Associates, on contract to DFO, performed the work at Tatsamenie and Tuya lakes.

## Tahltan Lake

Sampling and enumeration at Tahltan Lake was conducted from May 6 to June 30. A total of 829 smolts were sampled and heads were preserved for thermal mark analysis. An estimated 293,545 smolts originated from the fry planting program. The overall age composition of the smolts captured was $97.6 \%$ age $1+$ and $2.4 \%$ age $2+$ based on the scale age analysis (Table 9). Average lengths and weights were 83.4 mm and 106.8 mm , and 4.7 g and 9.6 g for age $1+$ and age $2+$ fish, respectively. The Tahltan smolt enumeration program uses a fence and modified inclined plane traps to capture all emigrating smolts. Volumetric displacement techniques are employed to determine the total smolt run size. The 1999 smolt population was estimated to be 762,033 (743,990 age $1+$ and 18,043 age $2+$ ).

## Tatsamenie Lake

Capture of smolts for sampling as well as for obtaining mark-recapture estimates was conducted from May 21 through July 1 using a fyke net, with attached wing nets. Of the 34,552 smolts captured, a total of 500 retained for sampling and the heads preserved for thermal mark analysis. The overall age composition of the smolts captured was $67.8 \%$ age $1+$ and $32.2 \%$ age $2+$ based on thermal mark analysis (Table 9). Of the 500 otoliths examined, 57 ( 17 fed BY97, 38 unfed BY97, and 2 unfed BY96) were thermally marked. The 1999 Tatsamenie smolt emigration was estimated using mark-recapture techniques. Smolt abundance was estimated (preliminary estimate using Darroch estimator) to be 776,296 (95\% CI +/- 84,737) with an enhanced component of 91,807 ( 47,542 unfed $1+$ and 44,309 fed $1+$ ) smolts. An undetermined portion of the run occurred prior to the start of the mark-recapture program.
A summary of preliminary data for the 1999 average length and weight for the transboundary sockeye smolts is presented in the Table 9.

## Trapper and Little Trapper Lakes

These lakes were not sampled in 1999.

## Tuya Lake

In 1999, emigrating smolts were captured with a fyke net from June 5 to June 25. A total of 120 were retained for length, weight, and scale samples. The heads from the sampled smolts were preserved for otolith analysis, although it is assumed all smolts were of enhanced origin. Based on scale analysis, the overall age composition was $81.4 \%$ age $1+$, $16.1 \%$ age $2+$, and $2.5 \%$ age $3+$ (Table 9).

## Short Term Fry Holding and Feeding Studies

Short-term pen holding studies were conducted at Tahltan and Tatsamenie lakes. The objective of this program was to determine post-transport mortality rates. At Tatsamenie, a total of 1,018,615 fry marked with an ancillary thermal mark was held and fed prior to release. The objective of feeding the fry was to increase the weight of the fry to determine if larger size at release confers an advantage that will increase fry to smolt survival.

## Tahltan Lake

Four shipments totaling 1,700,000 fry were made to Tahltan Lake between May 29 and June 2. The first three shipments of enhanced fry were held in net pens for 29-30 hours and fed every 812 hours prior to release. The estimated number of mortalities ( $7,000-8,000$ ) represented $0.5 \%$ to $0.6 \%$ of the $1,670,615$ fry, which were transported and held. The last shipment of fry was not held in a net pen due to extreme wind conditions, which made it difficult to maneuver the plane on the lake; the number of fry released in the last shipment totaled approximately 360,000 .

## Tatsamenie Lake

Four shipments totaling $1,800,000$ fry were made to Tatsamenie Lake June 1-9. The first shipment ( 606,313 fry) was held in a net pen for 20 days (a sub-sample was held for 30 days to determine the effectiveness of a new holding pen) and fed. The second shipment of fry $(399,974)$ was held for 32 hours and released while the third shipment ( 351,069 fry) was released immediately. The fourth shipment of fry was held and fed for 21 days before being released. The estimated number of holding mortalities was 137,100 (7.8\%) for all shipments combined.
The first shipment of fry attained release weights of 0.29 g and 0.50 g for the fry held 20 and 30 days, respectively. Estimated mortality for this group was 5,000 fry (0.8\%). The fourth shipment of fry attained a release weight of 0.25 g after 21 days of feeding. Estimated mortality for this group was 131,000 fry (31.8\%). Since these fish were marked with an ancillary thermal mark, it will be possible to determine if feeding and release at a larger size results in a survival rate that is higher than observed for the unfed release groups.

## Passive Flow Incubator - Tatsamenie Lake

For the second year, an experimental passive flow incubator was setup in Tatsamenie Lake approximately 300 m from the lake outlet. Approximately 34,000 sockeye salmon eggs were placed in the incubator in the fall of 1999.

## CENTRAL INCUBATION FACILITY

## Otolith Analysis

## U.S. Otolith Lab

During the 1999 season, ADF\&G thermal mark lab received 15,845 sockeye otoliths collected by ADF\&G and DFO staff as part of the U.S./Canada enhancement program. These collections came from commercial and test fisheries in U.S. waters and in Canadian fisheries on the Taku and Stikine Rivers over an 11-week period. In addition, cost recovery and rack samples from Snettisham Hatchery as well as several escapement samples were examined. Combined, the laboratory processed 14,131 of the otoliths received and provided estimates of hatchery contribution for 124 distinct sampling collections. Of these totals, 3,071 otoliths were identified and classified as belonging to one of 28 marking groups. Contribution estimates of the percentage of enhanced fish in the commercial openings were provided to ADF\&G and Canadian fisheries managers within 24 to 48 hours after sampling.

## Canadian Otolith Labs

The Whitehorse otolith laboratory received 2,164 otoliths from various Canadian transboundary river fisheries and sockeye escapements. In addition, 1,120 otoliths were collected from sockeye fry or smolt samples collected from Tatsamenie, Tahltan and Tuya lakes. The majority of the adult otolith analysis was completed by November of 1999. Juvenile samples, including approximately 900 juvenile otoliths collected from Tatsamenie, Trapper, and Tuya lakes in 1997-98, and 1,000+ adult otoliths from Tatsamenie, Tahltan and Tuya Lake sockeye salmon in 1997-98 were processed.

${ }^{\text {a }}$ Catches do not include Blind Slough terminal area harvests.
${ }^{\mathrm{b}}$ Effort may be less than the sum of effort from 106-41/42 and 106-30 since some boats fished in more than one subdistrict.
${ }^{\mathrm{c}}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

Appendix B. 6. Scale pattern based stock proportions and catches of sockeye salmon in the Alaskan District 106 commercial drift gillnet fisheries, 1982-1999.

${ }^{\text {a }}$ Days open are for the entire district and include openings to harvest spawner Chinook salmon, 1960-1975.
${ }^{\mathrm{b}}$ S Chum and F Chum refer to Summer and Fall runs of these fish, fish harvested prior to week 34 are considered summer chum, and fish harvested in week 34 and beyond are considered fall chum.

Appendix D. 2. Estimates of stock proportion and catch of sockeye salmon based on analysis of scale patterns, otolith marks, and brain parasite incidence, in the Alaska District 111 commercial drift gillnet fishery, 1983-1999.

${ }^{a}$ Weir count plus spawning ground survey.
${ }^{\mathrm{b}}$ Weir counts are incomplete.
${ }^{c}$ Counts may be low due to uncounted fish passage past weir.
${ }^{d}$ Mark-recapture estimates. .
${ }^{e}$ In 1995 the weir was moved upstream to Tatsamenie Lake, the count of 8,000 is an expansion (based on past experience) of the 5,780 fish counted there.
${ }^{\mathrm{f}}$ The estimated return of 10,381 through the Tatsamenie Lake weir in 1996 is thought to represent approximately $80 \%$ of the sockeye run past the old weir location at L.Tatsamenie. This results in a potential run of 12,976 sockeye salmon.
${ }^{\mathrm{g}}$ The estimated return of 8,363 through the Tatsamenie Lake weir in 1997 is thought to represent approximately $80 \%$ of the sockeye run past the old weir location at L . Tatsamenie Lake resulting in a potential run of 10,454 sockeye.
${ }^{\mathrm{h}}$ The estimated count of 5,997 fish through Tatsamenie Lake weir in 1998 does not include an estimated 1,499 fish spawning in the outlet stream i.e. total estimate 7,496.
${ }^{i}$ Minimum estimates of run size.

${ }^{\text {a }}$ Counts include jack Chinook salmon.
${ }^{\mathrm{b}}$ Includes sockeye counts up to and including August 15.
${ }^{\mathrm{c}}$ Weir was removed prior to the end of the coho run.
${ }^{\mathrm{d}}$ The Chinook and sockeye escapements into Klukshu Lake are calculated from the weir count minus fish harvested above the weir site minus brood stock taken. The remainder of the food fishery harvest occurred below the weir, at Village Creek, and Blanchard and Takhanne Rivers.

Appendix E. 8. Alsek River sockeye salmon counts from U.S. and Canadian aerial surveys and from the electronic counter at Village Creek, 1985-1999.

${ }^{\text {a }}$ Surveys not made every year at each tributary.
${ }^{\mathrm{b}}$ Includes several streams from Lo-Fog to Goat Creek.
${ }^{\text {c }}$ Incomplete count due to machine malfunction.
${ }^{d}$ Estimated count based on absolute electronic records $(5,313)$ and the total number of non-operational days.
${ }^{e}$ Estimated count based on absolute electronic records $(3,981)$ and the total number of non-operational days.
${ }^{\mathrm{f}}$ Counts were estimated during the non-operational days by averaging the counts recorded three days before and three days after the malfunction.
${ }^{\mathrm{g}}$ Estimated count based on absolute electronic records $(2,101)$ and the total number of non-operational days.
${ }^{h}$ Estimated count based on absolute electronic records $(3,921)$ and the total number of non-operational days.
${ }^{i}$ No counts due to a major malfunction of the counter

[^0]:    ${ }^{a}$ Tahltan includes wild and thermally marked fish.

[^1]:    ${ }^{a}$ Effort may be less than the sum of effort from 106-41\&42 and 106-30 because some boats fished in more than one subdistrict.
    ${ }^{\mathrm{b}}$ Catches do not include Blind Slough terminal area harvests.
    ${ }^{\text {c }}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

[^2]:    ${ }^{\text {a }}$ Sex specific age compositions were calculated and the stock composition of the females sampled for egg diameters was expanded to the catch by age.
    ${ }^{\mathrm{b}}$ Tahltan includes wild and planted fish.

[^3]:    ${ }^{\text {a }}$ Sex specific age compositions were calculated and the smoothed stock compositions of the females sampled for egg diameters was expanded to the catch by age.

[^4]:    ${ }^{9}$ Tahltan includes wild and thermally marked fish.

[^5]:    - continued -

[^6]:    ${ }^{\text {a }}$ Catches in 1979 were included in the lower river commercial catches.
    ${ }^{\mathrm{b}}$ There was no commercial fishery in 1984.
    ${ }^{\text {c }}$ Chinook average for 1975-1998 is for jacks and large fish combined.

[^7]:    ${ }^{\text {a }}$ Chinook average for 1972-1998 is for jacks and large fish combined.

[^8]:    ${ }^{\text {a }}$ Catches in 1979 were included in the lower river commercial catches.
    ${ }^{\mathrm{b}}$ There was no commercial fishery in 1984.

[^9]:    ${ }^{\mathrm{a}}$ There was no commercial fishery in 1984.
    ${ }^{\mathrm{b}}$ Chinook average for 1972-1998 is for jacks and large fish combined.

[^10]:    ${ }^{a}$ Average proportions are from averages of weekly stock composition and migratory timing (from drift test fishery) estimates.
    ${ }^{\text {b }}$ Stock compositions based on: scale circuli counts 1979-1983; SPA in 1985; average of SPA and GPA 1986-1988; and egg diameter analysis in 1989-1999. 1994-1999 data from commercial catch and CPUE.

[^11]:    - continued -

[^12]:    ${ }^{\text {a }}$ Stock composition estimates are historical (1983-1998) averages, except for planted which are based on marked fish expansions.

[^13]:    ${ }^{\text {a }}$ Aboriginal catch by week is not available.
    ${ }^{\mathrm{b}}$ Expansion based on proportion of coho troll harvest taken through statistical week 37, known to be minimum since troll catch rates were still high when the troll fishery closed for season.
