## LIST OF APPENDICES

Appendix Page
Appendix A. 1. Weekly salmon catch and effort in the Alaskan Subdistrict 106-41\&42 (Sumner Strait) commercial drift gillnet fishery, 1996 ..... 49
Appendix A. 2. Weekly stock proportions and catches of sockeye salmon harvested in the Alaskan Subdistrict 106-41\&42 (Sumner Strait) commercial drift gillnet fishery, 1996. Data based on scale pattern analysis. ..... 49
Appendix A. 3. Weekly salmon catch and effort in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 1996 ..... 50
Appendix A. 4. Weekly stock proportions and catches of sockeye salmon harvested in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 1996. Data based on scale pattern analysis ..... 50
Appendix A. 5. Weekly salmon catch in the Alaskan District 106 commercial drift gillnet fisheries, 1996. Catches do not include blind Slough terminal area harvests. Effort may be less than the sum of effort from 106-41\&42 and 106-30 because some boats fished in more than one subdistrict. ..... 51
Appendix A. 6. Weekly salmon catch contributions of Alaska hatchery and wild fish to the Alaskan District 106 commercial drift gillnet fisheries, 1996. Catches do not include blind Slough terminal area harvests. Effort may be less than the sum of effort from 106- 41\&42 and 106-30 because some boats fished in more than one subdistrict. ..... 52
Appendix A. 7. Weekly stock proportions of sockeye salmon harvested in the Alaskan District 106 commercial drift gillnet fisheries, 1996. Data based on SPA ..... 53
Appendix A. 8. Weekly salmon catch and effort in the Alaskan District 108 commercial drift gillnet fishery, 1996. Catches do not include Ohmer Creek terminal area harvests. The permit days are adjusted for boats that did not fish the entire opening and are less than the sum of the permits times the days open ..... 54
Appendix A. 9. Weekly salmon catch contributions of Alaska hatchery and wild fish to the Alaskan District 108 commercial drift gillnet fishery, 1996. Catches do not include Ohmer Creek terminal area harvests. The permit days are adjusted for boats that did not fish the entire opening and are less than the sum of the permits times the days open. .. 55
Appendix A. 10. Weekly stock proportions and stock-specific catch of sockeye salmon in the Alaskan District 108 commercial drift gillnet fishery, 1996. Catches do not include Ohmer Creek terminal area harvests. Data based on SPA. ..... 56
Appendix A. 11. Weekly salmon and steelhead trout catch and effort in the Canadian commercial fishery in the lower Stikine River, 1996 ..... 57
Appendix A. 12. Weekly sockeye salmon stock proportions and catch by stock in the Canadian commercial fishery in the lower Stikine River, 1996. Sex specific age compositions were calculated and the stock composition of the females sampled for egg diameters was expanded to the catch by age. Thermal mark information based on recovery ratios of Tahltan and Tuya fish in 108. ..... 58
Appendix A. 13. Weekly salmon and steelhead trout catch and effort in the Canadian commercial fishery in the upper Stikine River, 1996 ..... 59
Appendix A. 14. Weekly salmon and steelhead trout catch and effort in the Canadian Aboriginal fishery located at Telegraph Creek, on the Stikine River, 1996 ..... 59
Appendix A. 15. Catch by stock by week for sockeye salmon harvested in the Canadian upper river commercial and Aboriginal fisheries in the Stikine River, 1996. ..... 60
Appendix A. 16. Weekly salmon and steelhead trout catch and effort in the Canadian test fishery in the Stikine River, 1996 ..... 61
Appendix A. 17. Weekly catch, CPUE, and migratory timing of Tahltan and Mainstem sockeye salmon stocks in the Stikine River test fishery, 1996. Sex specific age compositions were calculated and the smoothed stock compositions of the females sampled for egg diameters were expanded to the catch by age ..... 62
Appendix A. 18. Daily counts of adult sockeye salmon passing through Tahltan Lake weir, 1996. ..... 63
Appendix A. 19. Daily counts of sockeye salmon smolt migrating through Tahltan Lake smolt weir, 1996 ..... 64
Appendix A. 20. Daily counts of adult Chinook salmon passing through Little Tahltan weir, 1996 ..... 65
Appendix B. 1. Salmon catch and effort in the Alaskan Subdistrict 106-41 and -42 (Sumner Strait) commercial drift gillnet fishery, 1960-1996 ..... 67
Appendix B. 2. Stock proportions and catches of sockeye salmon in the Alaskan Subdistrict 106-41 and -42 (Sumner Strait) commercial drift gillnet fishery, 1985-1996. Data based on SPA. ..... 68
Appendix B. 3. Salmon catch and effort in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 1960-1996 ..... 69
Appendix B. 4. Stock proportions and catches of sockeye salmon in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 1985-1996. Data based on SPA. ..... 70
Appendix B. 5. Salmon catch and effort in the Alaskan District 106 commercial drift gillnet fisheries, 1964-1996. Catches do not include Blind Slough terminal area harvests. Effort may be less than the sum of effort from106-41/42 and 106-30 since some boats fished in more than one subdistrict. ..... 71
Appendix B. 6. Stock proportions and catches of sockeye salmon in the Alaskan District 106 commercial drift gillnet fisheries, 1982-1996. Catches do not include Blind Slough terminal area harvest. Data based on SPA. ..... 72
Appendix B. 7. Salmon catch and effort in the Alaskan District 108 commercial drift gillnet fishery, 1960-1996. Catches do not include Ohmer Creek terminal area harvests. Permit days are adjusted for boats which did not fish the entire opening and may total less than the sum of the permits times days open ..... 73
Appendix B. 8. Stock proportions and catches of sockeye salmon in the Alaskan District 108 commercial drift gillnet fishery, 1985-1996. Catches do not include Ohmer Creek terminal area harvests. Data based on SPA ..... 74
Appendix B. 9. Salmon catch in the Alaskan District 106 and 108 test fisheries, 1984-1996. Only years with test fishery openings are listed. ..... 75
Appendix B. 10. Stock proportions of sockeye salmon in the Alaskan District 106 and 108 test fisheries, 1984-1996. Data based on SPA. Only years with test fishery openings are listed ..... 76
Appendix B. 11. Stock specific catches of sockeye salmon in the Alaskan District 106 and 108 test fisheries, 1984-1996. Data based on SPA. Only years with test fishery openings are listed ..... 77
Appendix B. 12. Salmon and steelhead trout catch and effort in the Canadian commercial fishery in the lower Stikine River, 1979-1996. ..... 78
Appendix B. 13. Sockeye salmon stock proportions and catch by stock in the Canadian commercial fishery in the lower Stikine River, 1979-1995. Stock compositions based on: scale circuli counts 1970-1983; SPA in 1985; average of SPA and GPA 1986; SPA in 1987 and 1988; and egg diameter in 1989-1996. ..... 79
Appendix B. 14. Salmon and steelhead trout catch and effort in the Canadian commercial fishery in the upper Stikine River, 1975-1996. ..... 80
Appendix B. 15. Salmon and steelhead trout catch in the Canadian Aboriginal fishery located at Telegraph Creek, on the Stikine River, 1972-1996. ..... 81
Appendix B. 16. Catch by stock for sockeye salmon harvested in the Canadian upper river commercial and Aboriginal fisheries in the Stikine River, 1972-1996 ..... 82
Appendix B. 17. Salmon and steelhead trout catch in the combined Canadian net fisheries in the Stikine River, '1972-1996. ESSR catches not included ..... 83
Appendix B. 18. Salmon catches in the Stikine River harvested under Canadian ESSR licenses, 1992- 1996 ..... 83
Appendix B. 19. Salmon and steelhead trout catches and effort in Canadian test fisheries in the Stikine River, 1985-1996. ..... 84
Appendix B. 20. Sockeye salmon stock proportions and catch by stock in the test fishery in the lower Stikine River, 1985-1995. Stock composition based on: SPA 1985; average of SPA and GPA 1986-1988; egg diameter 1989-1996 ..... 85
Appendix B. 21. Estimated proportion of inriver run comprised of Tahltan Lake and Mainstem sockeye stocks, 1979-1995. Stock compositions based on: scale circuli counts 1979-1983; SPA in 1985; average of SPA and GPA 1986-1988; and egg diameter analysis in 1989-1996. 1994-1996 data from commercial catch and CPUE ..... 85
Appendix B. 22. Counts of adult sockeye salmon migrating through Tahltan Lake weir, 1959-1996. ..... 86
Appendix B. 23. Aerial survey counts of Mainstem sockeye stocks in the Stikine River drainage, 1984-1996. The index represents the combined counts from eight spawning areas ..... 87
Appendix B. 24. Estimates of sockeye salmon smolt migrating through Tahltan Lake smolt weir, 1984-1996 ..... 87
Appendix B. 25. Weir counts of Chinook salmon at Little Tahltan River, 1985-1996 ..... 88
Appendix B. 26. Index counts of Stikine Chinook escapements, 1979-1996. Counts do not include jacks (fish less than 600mm mef length) ..... 89
Appendix B. 27. Index counts of Stikine coho salmon escapements, 1984-1996. Missing data due to poor survey conditions ..... 89
Appendix B. 28. Stikine River sockeye salmon run size, 1979-1996. Catches include test fishery catches. ..... 90
Appendix C. 1. Weekly salmon catch and effort in the Alaskan District 111 and Subdistrict 111-32 (Taku Inlet), commercial drift gillnet fishery, 1996 ..... 92
Appendix C. 2. Estimate of the proportion of natural and planted sockeye salmon stock groups harvested in the Alaskan District 111 commercial drift gillnet fishery by week, 1996. Stock composition based on 1983-1995 averages ..... 93
Appendix C. 3. Weekly stock-specific catch of wild and planted Taku River and Port Snettisham sockeye salmon harvested in the Alaskan District 111 commercial drift gillnet fishery, 1996. Stock composition estimates are historical (1983-1994) averages, except for planted which are based on marked fish expansions ..... 93
Appendix C. 4. Weekly salmon and steelhead trout catch and effort in the Canadian commercial fishery in the Taku River, 1996 ..... 94
Appendix C. 5. Weekly stock proportions of sockeye salmon harvested in the Canadian commercial fishery in the Taku River, 1996. ..... 94
Appendix C. 6. Weekly stock-specific catch of sockeye salmon in the Canadian commercial fishery in the Taku River, 1996 ..... 95
Appendix C. 7. Mark-recapture estimate of above border run of sockeye and coho salmon in the Taku River, 1996. The early season sockeye salmon expansion is based on the proportion of fish wheel sockeye salmon catch that occurs before the fishery opens and the late season expansion for coho salmon is based on the proportion of the CPUE of above border coho salmon stocks in the District 111-32 fishery that occurs after the tagging is stopped ..... 95
Appendix C. 8. Daily counts of adult salmon passing through Tatsamenie weir, 1996. ..... 96
Appendix C. 9. Daily counts of adult sockeye salmon passing through Little Trapper Lake weir, 1996. ..... 97
Appendix C. 10. Daily counts of adult salmon passing through the Nahlin River weir, 1996. Chinook salmon counts represent an unknown portion of the escapement because the weir was not operated throughout the entire run. ..... 98
Appendix C. 11. Daily counts of adult sockeye salmon passing through the Kuthai Lake weir, 1996. ..... 99
Appendix D.1. Salmon catches and effort in the Alaskan District 111 and Subdistrict 111-32 (Taku Inlet) commercial drift gillnet fishery, 1960-1996. Days open are for the entire district and include openings to harvest spawner Chinook salmon, 1960-1975. ..... 101
Appendix D. 2. Stock proportions and catches of sockeye salmon in the Alaska District 111 commercial drift gillnet fishery, 1983-1996. Data based on analysis of scale patterns, otolith marks, and incidence of brain parasites ..... 103
Appendix D. 3. Proportion of wild Taku River sockeye salmon in the Alaskan District 111 commercial drift gillnet catch by week, 1983-1996. Data based on scale patterns and incidence of brain parasites. ..... 104
Appendix D. 4. Salmon catch in the U.S. subsistence and personal use fisheries in the Taku River, 1967-1996. The subsistence fishery was open 1967 to 1976 and 1985 and the personal use fishery was open 1989-1996. ..... 104
Appendix D. 5. Salmon and steelhead trout catch and effort in the Canadian commercial fishery in the Taku River, 1979-1996. ..... 105
Appendix D. 6. Sockeye salmon stock proportions and catch by stock in the Canadian commercial fishery on the Taku River, 1986-1996. Data based on scale pattern analysis. ..... 106
Appendix D. 7. Salmon catches in the Canadian Aboriginal fishery on the Taku River, 1980-1996. ..... 107
Appendix D. 8. Salmon and steelhead trout catch in the Canadian test fishery in the Taku River, 1987-1996. ..... 107
Appendix D. 9. Taku River sockeye salmon run size, 1984-1996. Run estimate does not include spawning escapements below the U.S./ Canada border. The early season sockeye salmon expansion is based on the proportion of fish wheel sockeye salmon catch that occurs before the fishery opens. ..... 108
Appendix D. 10. Sockeye salmon escapement estimates of Taku River and Port Snettisham sockeye salmon stocks, 1979-1996. Spawners equals escapement to the weir minus fish collected for brood stock. ..... 108
Appendix D. 11. Aerial survey index escapement counts of large (3-ocean and older) Taku River Chinook salmon, 1975-1996. ..... 109
Appendix D. 12. Taku River (above border) coho salmon run size, 1987-1996. ..... 109
Appendix D. 13. Escapement counts of Taku River coho salmon, 1984-1996. Counts are for age-. 1 fish and do not include jacks. Because of variability between methods, visibility, observers, and timing, these counts are not an index of run strength. ..... 110
Appendix D. 14. Canyon Island fish wheel salmon counts and periods of operation on the Taku River, 1983-1996. ..... 110
Appendix E. 1. Weekly salmon catch and effort in the U.S. commercial fishery in the Alsek River, 1996. ..... 112
Appendix E. 2. Weekly salmon catch and effort in the Canadian Aboriginal and sport fisheries in the Alsek River, 1996. Total catches do not include released fish. ..... 112
Appendix E. 3. Daily counts of salmon passing through Klukshu River weir, 1996. ..... 113
Appendix E. 4. Salmon catch and effort in the U.S. commercial fishery in the Alsek River, 1960- 1996. ..... 115
Appendix E. 5. Salmon catch in the U.S. subsistence and personal use fisheries in the Alsek River, 1976-1996. Catches are those reported on returned permits. ..... 116
Appendix E. 6. Salmon catches in the Canadian Aboriginal and sport fisheries in the Alsek River, 1976-1996. ..... 116

| TAC | Total Allowable Catch |
| TRTFN | Taku River Tlingit First Nation |
| TBR | Transboundary River |
| TTC | Transboundary Technical Committee |
| PSC | Pacific Salmon Commission |

## EXECUTIVE SUMMARY

Estimates of catches and escapements of Pacific salmon returning to the transboundary Stikine, Taku, and Alsek rivers for 1996 are presented and compared with historical patterns. Relevant information pertaining to the management of appropriate U.S. and Canadian fisheries is presented and the use of inseason management models is discussed. Results from transboundary river sockeye salmon Oncorhynchus nerka enhancement projects are also reviewed.

## STIKINE

The 1996 Stikine sockeye salmon run is estimated at 372,300 fish, of which 264,000 fish were harvested in various fisheries, 4,400 were used for broodstock, and 108,300 escaped to spawn. The catch was the highest recorded since 1982 when stock identification techniques were first used for marine catches. The run was the highest since 1979 and was above the 1986-1995 average of 141,400 sockeye salmon. The estimated U.S. commercial catch of Stikine sockeye salmon in Districts 106 and 108 was 188,400 fish; the Canadian inriver commercial, aboriginal, Excess Salmon to Spawning Requirement (ESSR), and test fishery catches were 67,400, 6,900, 13,200 and 1,300 fish, respectively. Sockeye salmon from outplants into Tahltan and Tuya lakes contributed an estimated 36,000 fish to U.S catches and 15,400 fish to Canadian catches. The postseason estimate of 372,300 sockeye salmon was slightly above the preseason forecasts by Canada $(329,000)$ and the U.S. $(341,000)$. The Stikine Management Model correctly predicted a larger than average sockeye salmon run. Weekly inseason model forecasts ranged from 220,500 to 493,000 sockeye salmon; the final inseason model predictions were 336,700 (Canada) and 360,500 (U.S.). Canadian and U.S. final inseason estimates were different primarily due to differences in commercial catch data input. Using the inseason estimates, both countries were harvesting below their TAC, with the exception of the U.S. final model run in statistical week 32. Using the postseason estimate of run size and total allowable catch, Canada harvested $24 \%$ of the total allowable catch and the U.S. harvested $60 \%$ of the total allowable catch. The broodstock take removed 4,400 sockeye salmon, and terminal surplus escapement fishery removed 13,200 sockeye salmon from the escapement to Tahltan Lake leaving a spawning escapement of 52,500 fish, $219 \%$ above the goal of 24,000 fish. The estimated spawning escapement of 45,200 Mainstem Stikine sockeye salmon was above the upper end of the escapement goal range (20,000 to 40,000 fish) for this stock group.
The catch of Chinook salmon O.tshawytscha in Canadian commercial and aboriginal fisheries in the Stikine River was 2,500 large fish and 420 jacks, $24 \%$ above and $24 \%$ below the respective 1986-1995 averages. An additional 50 Chinook salmon were taken in the Canadian inriver test fishery. The U.S. marine catch of Chinook salmon in the District 106 and 108 mixed stock gillnet fisheries was 2,400 fish, approximately $5 \%$ above the 1986-1995 average catch. The Chinook salmon spawning escapement of 4,800 large adults through the Little Tahltan River weir in 1996 was $10 \%$ below the 1986-1995 average and $4 \%$ below the joint U.S./Canada escapement goal of 5,300 fish. Surveys of other Stikine tributaries also showed below average escapements.
The U.S. marine harvest of Stikine River coho salmon $O$. kisutch is unknown since there is no stock identification program for this species; however, total mixed-stock coho salmon catches of 223,600 and 19,100 fish in Districts 106 and 108, respectively, were 34\% and $40 \%$ above the 1986-1995 averages. Alaskan hatchery fish comprised approximately $23 \%$ ( 55,900 fish) of the coho salmon harvest from the two districts. The Canadian inriver coho salmon catch of 1,400
fish was $41 \%$ of the previous 10 -year average. The estimated coho salmon escapement of 59,600 fish is above the interim escapement goal range of 30,000 to 50,000 coho salmon. Aerial surveys of six coho salmon spawning index sites also indicated above average spawning escapement.

## TAKU

The 1996 Taku sockeye salmon run estimate was 324,800 fish, a record, and included an estimated catch of 232,200 fish and an above-border spawning escapement of 92,600 fish. The run size and catch were all time highs, and escapement, while below the 1986-1995 average, exceeded the upper level of the escapement goal range of 71,000 to 80,000 fish. An estimated 187,400 Taku sockeye salmon were taken in the District 111 commercial fishery and 3,000 sockeye salmon in the U.S. inriver personal use fisheries. Canadian inriver commercial and aboriginal fishery catches were 41,000 and 400 sockeye salmon, respectively. Since the escapement goal is expressed as a range, the resulting total allowable catch is also expressed as a range. In 1996, Canada harvested an estimated $17 \%$ to $17.2 \%$, and the U.S. took $75 \%$ to $78 \%$ of the total allowable catch.

The catch of large Chinook salmon in the Canadian commercial fishery in the Taku River was 3,300 fish, over 3 times the 1986 to 1995 average; in addition, 140 jack Chinook salmon were caught compared to an average of 190 fish. The District 111 mixed stock gillnet fishery harvested 2,700 Chinook salmon, $21 \%$ below the 1986-1995 average. Twenty percent of the catch was estimated to be of Alaska hatchery origin. Escapement observed in six Taku River Chinook salmon index tributaries was the highest recorded. The combined aerial count for the index tributaries was 19,800 fish, which was two times the 1986-1995 average of 9,700 fish, and 1.5 times the index escapement goal of 13,200 fish.

The Taku coho salmon run was below the 1986 to 1995 average in 1996. The U.S. harvest of 33,600 coho salmon in the District 111 mixed stock fishery was $39 \%$ of the previous 10 -year average and the lowest catch since 1986. Alaskan hatcheries contributed an estimated $23 \%$ of the District 111 harvest, or 7,600 fish. The Canadian inriver commercial and food fishery catch was 24 coho salmon, $27 \%$ of the previous 10 -year average. The above-border inriver run size is estimated at 49,700 coho salmon. After upriver Canadian catches are subtracted from the inriver run, the above-border spawning escapement is estimated at 44,600 coho salmon, which exceeds the interim escapement goal range of 27,500 to 35,000 fish.

The catch of pink salmon O. gorbuscha in District 111 was 12,700 fish, 7\% of the 1986-1995 average catch. There was no reported harvest of pink salmon in the Canadian commercial inriver fishery. The escapement of pink salmon to the Taku River was good as evidenced by the fish wheel catch of 21,600 pink salmon, $33 \%$ above the ten-year average.
The catch of chum salmon $O$. keta in the District 111 fishery was 354,100 fish, composed of 347,600 summer run fish (prior to mid-August) and 6,500 fall run fish. The catch of summer chum salmon, primarily Alaskan hatchery stocks, was a new record, slightly above the 1995 record catch. The catch of fall chum salmon, composed of wild Taku River and Port Snettisham stocks, was $76 \%$ below the 1986-1995 average. There was no reported harvest of chum salmon in the Canadian inriver fishery. Escapement appeared to be poor; the Canyon Island fish wheel catch of 400 chum salmon was $62 \%$ below average.

## Alsek

The Alsek River sockeye salmon harvest of 15,000 fish was about 17\% below the 1986-1995 average of 18,000 . Canadian catches of 1,200 sockeye salmon in the aboriginal fishery and 200 in the sport fishery were $38 \%$ and $60 \%$ below average, respectively. The escapement to the Klukshu River weir of 8,300 fish was $45 \%$ below the 1986-1995 average. The Klukshu weir counts of 1,500 early-run (count through August 15) and 6,800 late-run sockeye salmon were both 45\% below the 1986-1995 averages.

The Chinook salmon run to the Alsek River seemed above average. The U.S. Dry Bay catch of 800 fish was more than double the 1986-1995 average. The combined Canadian sport and aboriginal fishery catch of 1,100 fish was $86 \%$ above the 1986-1995 average. The 3,600 Chinook salmon count through the Klukshu River weir was $27 \%$ above the 1986-1995 average of 2,800 fish. The Klukshu River escapement goal is 4,700 Chinook salmon. Aerial survey index counts of other spawning systems were below average.

The coho salmon run to the Alsek River was above average, but current stock assessment programs prevent an accurate comparison with historical runs. The U.S. Dry Bay catch of 5,500 coho salmon was $23 \%$ above the 1986-1995 average, while the combined Canadian inriver aboriginal and sport fishery catch of 65 fish was $62 \%$ below the 1986-1995 average; the coho salmon fishery was restricted due to efforts to protect the low return of sockeye salmon. Operation of the Klukshu weir does not provide a complete enumeration of coho salmon into this system since it is removed before the run is over; however, the count of 3,500 coho salmon was the third highest count on record.

## ENHANCEMENT

Eggs and milt were collected from the 1996 sockeye salmon escapements to Tahltan and Tatsamenie lakes. A total of 6.2 million eggs was collected at Tahltan Lake, slightly above the 6.0 million egg-take goal. The Tatsamenie Lake egg-take goal was increased to 5.0 million from the old goal of 2.5 million; the new goal was realized in 1996 with the collection of 5.0 million eggs.

Outplants of 1995 broodyear sockeye salmon fry in June and July 1996 included 2,300,000 fry in Tahltan Lake, 2,500,000 fry of Tahltan Lake origin in Tuya Lake, and 1,700,000 fry in Tatsamenie Lake. Green-egg to planted-fry survivals were $76 \%$, $64 \%$, and $72 \%$ for these outplants, respectively. Survival to emergence was below average partially due to the loss of 852,000 fry due to Infectious Hematopoietic Necrosis (IHN). Losses from IHN have occurred in the past at Snettisham Hatchery and are expected in sockeye salmon culture; Snettisham Hatchery has a good history of minimal losses to IHN.

Sampling of outmigrating smolts was conducted at lake systems that had been stocked with sockeye salmon fry. Large numbers of sockeye salmon smolts were captured at all lakes except Trapper Lake. Total emigration was estimated for Tahltan Lake and Tatsamenie Lakes in 1996. An estimated 1,559,000 smolts emigrated from Tahltan Lake; an estimate of the number from fry plants is not yet available. At Tatsamenie Lake a smolt recapture program was tested and provided an estimate of 469,000 emigrant smolts; this project was only funded for one year and while successful, may not be continued. As in past years, smolts outmigrating from Tuya Lake this spring were large in size. Outmigrating smolts were captured from Trapper Lake in 1996 as
in previous years; age analysis is not complete, however, there appeared to be a higher proportion of age- 1 smolts.

The State of Alaska transferred the operation of Snettisham from Alaska Department of Fish and Game (ADF\&G) to Douglas Island Pink and Chum, Inc. (DIPAC), a private aquaculture organization with two other operational hatcheries in Juneau. A cooperative agreement between ADF\&G and DIPAC provides for Snettisham to continue to serve the needs of the joint transboundary river enhancement projects. The transfer took effect on July 1, 1996; the new managers are doing an excellent job of hatchery operation. The egg incubation and thermal marking program at Snettisham Hatchery went smoothly in 1996.
Adult sockeye salmon otoliths were processed inseason by the Alaska Department of Fish and Game otolith lab to estimate the weekly contribution of enhanced sockeye salmon returns to the District 106, 108, and 111 gillnet fisheries. Canadian Department of Fisheries and Oceans’ otolith lab will be processing all 1996 transboundary adult, juvenile, and smolt otolith samples.

## INTRODUCTION

This report presents estimates of the 1996 catch and escapement data for Pacific salmon runs to the transboundary Stikine, Taku, and Alsek rivers and discusses management actions taken during the season. Catch and effort data are presented by management week (U.S. statistical week) for each river for both U.S. and Canadian fisheries. Spawning escapement data for most species are reported from weir counts or other escapement monitoring techniques. Sockeye salmon runs to the three rivers are reconstructed using harvest data and spawning escapement estimates. Joint enhancement activities on the Stikine and Taku rivers are also summarized.
Run reconstruction analyses are conducted on the sockeye salmon runs to the three rivers for the purpose of evaluating the stocks and the fisheries managed for these stocks. No estimates of marine catch are made for Alaskan fisheries outside of District 106 and 108 for Stikine stocks, District 111 for Taku stocks and Subdistrict 182-30 \& 31 for Alsek stocks. Therefore, the total catches of transboundary stocks made for this report will not match estimates made for the Joint Interception Committee Report.

## STIKINE RIVER

Stikine River salmon are harvested by U.S. gillnet fisheries in Alaskan Districts 106 and 108, by Canadian commercial gillnet fisheries located in the lower and upper Stikine River, and by a Canadian Aboriginal fishery in the upper portion of the river (Figure 1). A small sport fishery also exists in the Canadian portion of the Stikine drainage. In 1995, a United States personal use fishery was established in the lower Stikine River; no catches were reported in this fishery in 1995 and 1996. Additional catches of unknown quantity are taken in U.S. troll and seine fisheries and in sport fisheries near Wrangell and Petersburg. In 1996, the spring experimental troll area in District 9 portion of Frederick Sound was expanded to target hatchery Chinook salmon.

## Harvest Regulations and the Joint Management Model

Harvest arrangements for Stikine salmon were not negotiated by the Pacific Salmon Commission or Canadian and United States governments prior to the 1996 season. As a result, the Parties unilaterally developed the following management plans for the 1996 season:

1) Canada developed a fishing plan for the Stikine River that adopted the arrangements for sockeye salmon (which had not expired) but excluded the catch ceiling for coho salmon which had expired in 1992 ( 4,000 pieces). The harvest-sharing objective for the sockeye salmon season was to share the total allowable catch (TAC) of Stikine River sockeye salmon $50 \%$ to Canada and $50 \%$ to the United States. In the event that there was sockeye salmon surplus to spawning requirements at Tahltan Lake, attempts would be made to harvest some of the surplus. The plan did not permit targeting on Chinook salmon since both Parties had previously agreed to rebuild Chinook salmon by 1995. The joint assessment of the status of rebuilding efforts has not yet been completed.
2) The United States management plan was to abide by the harvest sharing provisions that were in effect in 1993; namely to harvest $50 \%$ of the TAC of Stikine sockeye salmon, to incidentally harvest Chinook salmon and to provide for a Canadian harvest of 4,000 coho salmon.

In previous years, the Transboundary Technical Committee (TTC) met prior to the season to update joint management and enhancement plans and determine new parameters for input into the inseason run forecast model, referred to as the Stikine Management Model (SMM). However, due to uncertainty regarding Pacific Salmon Commission deliberations, a joint management plan was not published in 1996.

Preseason forecasts of Stikine sockeye salmon abundance and updates to the SMM update were made jointly by the TTC during the preseason management meeting. Minor revisions to the forecasts were made independently by the Parties as more information became available.

In 1996, the preseason forecasts were used during statistical week 24 (June 09 to June 15) through statistical week 26 (June 23 to June 29). Beginning the first week of July, inseason forecasts of total run size and TAC, produced by the SMM and based on catch per unit effort (CPUE) data, were used to assist in determining weekly fishing plans (Table 1). The weekly inputs to the model included: the catch, effort and stock composition (proportion Tahltan) in the Canadian lower river test and commercial fisheries; the upper river catch in the Aboriginal fishery (AF) and upper river commercial fishery; the catch, effort and assumed stock composition in Subdistrict 106-41; and, the catch and assumed stock composition in District 108 and Subdistrict 106-30. Initially, average stock proportions from the postseason SPA analysis in previous years were assumed for weekly catches; the averages used each week depended upon whether the run was judged to be below average, average or above average. However, the Tahltan stock proportions were subsequently adjusted inseason based on the analysis of otolith samples taken in Districts 106 and 108. Inseason otolith sampling was conducted to estimate the contribution of enhanced Tahltan and Tuya Lake sockeye salmon to catches in these areas. The weekly estimate of Tuya fish in 106-41 was added to the historical proportion of Tahltan in the SMM since this stock was not in present in the historical database. No adjustments were made in District 108. Because different proportions

Figure 1. The Stikine River and principal U.S. and Canadian fishing areas.
of Tahltan fish were observed in subdistricts of 108, the overall contribution estimates for 108 were weighted according to catches in the subdistricts.

The preseason forecasts of returning Stikine sockeye salmon ranged from 329,000 (Canada) to 341,000 (U.S.) fish; both predictions indicated a run size substantially above the 1986-1995 average terminal run size of 141,426 (Appendix B.28). Canadian inseason predictions of total run ranged from 232,000 sockeye salmon to 476,000 sockeye salmon; U.S. forecasts ranged from 220,000 to 493,000 sockeye salmon. All forecasts indicated an above average run and most of the forecasts were above the preseason estimate. U.S. and Canadian weekly predictions differed primarily because of differences in commercial catch data inputs. Both Parties used the forecast based on inriver test fishery CPUE data for statistical week 27 and then switched to the forecasts derived from lower Stikine commercial fishery CPUE. The differences in the forecasts used are summarized in the table below.

Analyses of the forecasts developed in Canada indicated the forecasts based on inriver commercial and test fishery CPUE and District 106 CPUE differed throughout the season with the greatest variation occurring during the statistical week 28-30 period. The greatest variation in forecasts occurred between inriver commercial and district based forecasts (average absolute difference $=79,000$ ), whereas, the least variation occurred between test fishery and District 106 based forecasts (average absolute difference $=22,000$ ). By the end of August, i.e. statistical week 35 , the SMM predicted a total run of 275,000 based on inriver test fishery CPUE) to 337,000 sockeye salmon (based on inriver commercial CPUE). The forecast derived from District 106 CPUE was 314,000 sockeye salmon. Final estimates of the TAC ranged from 283,000 to 306,000 fish (Canada and U.S. model runs, respectively), with a Canadian and U.S. allowable harvest of 141,500 to 153,000 sockeye salmon each.
The SMM also predicts the Tahltan portion of the run independently from the total run forecasts. Canadian estimates of the Tahltan run ranged from 126,000 (statistical week 27) to 245,000 (statistical week 27) sockeye salmon compared to the preseason forecasts of 223,000 (Canada) and 273,000 (U.S.). The final inseason prediction of the Tahltan Lake weir count was 31,000 to 51,000 sockeye salmon (Canadian inriver Tahltan run forecasts based on District 106 and inriver commercial CPUE minus inriver catch) compared to the actual Tahltan Lake weir count of 52,500 fish. The Tahltan run forecasts based on test fishery data were ignored due to the small sample sizes used in the weekly stock ID estimates.

## U.S. FISHERIES

The 1996 harvest in the District 106 commercial gillnet fishery included 644 Chinook, 311,100 sockeye, 223,640 coho, 188,035 pink O. gorbuscha, 283,290 chum O. keta, and 130 steelhead salmon O. mykiss (Figure 2, Appendix A.5). In the District 108 fishery, 1,717 Chinook, 154,150 sockeye, 19,059 coho, 37,651 pink, 135,623 chum, and 40 steelhead salmon were harvested (Appendix A.7). District 106 catches of Chinook and pink salmon were below the 1986 to 1995 average while the catches of all other species were above the average. The sockeye salmon catch was the highest on record, the chum salmon catch was the second highest on record, behind 1995, and the coho salmon catch was the fourth highest on record (Figure 2). District 108 catches of all salmon species were above the 1986-1995 average with both the sockeye and chum salmon catch being the highest on record and the coho salmon catch being the sixth highest on record (Figure 2). Annual commercial and test fishery catches from 1964 to 1995 for these fisheries are provided in Appendices B. 1 through B.11. Catches of each species in Districts 106
and 108 consist of fish of mixed stock origin; the contribution of Stikine River stocks is estimated only for sockeye salmon (Figure 3). Scales were sampled from the various subdistricts and were used for making postseason catch estimates. The proportion of the District 106 and 108 sockeye salmon catch of Stikine River origin was estimated inseason using both the historical proportions of each stock and the thermally marked otoliths from returns of enhanced Tahltan and Tuya Lake sockeye salmon found in the catch.

The final inseason estimate of the contribution of Stikine sockeye salmon to Districts 106 and 108 was 178,625 or $38 \%$ of the sockeye salmon catch. The postseason estimate is 188,385 fish, $40.0 \%$ of the sockeye salmon catch (Figure 3, Appendices B. 6 and B.8). The Sumner Strait fishery (Subdistricts 106-41 \& 42) harvested 61,768 Stikine sockeye salmon (Appendices A. 2 and B.2), $28 \%$ of the total sockeye salmon harvest in that subdistrict; the Clarence Strait fishery (Subdistrict 106-30) harvested 840 Stikine sockeye salmon (Appendices A. 4 and B.4), 1.0\% of the catch in that subdistrict; and the District 108 fishery, near the mouth of the Stikine, harvested 125,777 Stikine sockeye salmon (Appendix A. 8 and B.8), 82\% of the District 108 catch.

The 1996 fishing season in District 108 began on June 10 (statistical week 24) and the District 106 fishing season began on June 16 (statistical week 25) and the fisheries in both districts continued through September 24 (statistical week 39). The District 108 fishery was open for one day during the initial opening (statistical week 24, June 10 to June 16); the opening was based on the preseason expectation of a U.S. TAC of 143,500 Stikine River sockeye salmon. Both districts were open for two days on the first general opening (statistical week 25). The initial opening in District 106 is normally two days and any decision to extend fishing is based on fishery catch rates estimated by management biologists on site in the fishery. During statistical weeks 25 and 26 (June 16 to 22) District 106 was restricted to a two-day per week fishery. During statistical weeks 27 and 28 District 106 was initially open for two days and then a portion of Sumner Strait (subdistricts 106-41 and 42) from MacNamara Pt to the District 106\&108 boundary was reopened for a 3.5 -day mid-week opening. District 106 was open for 3 days during statistical weeks 29 through 36 (July 14 to September 7) and for two days during statistical weeks 37 through 39. District 108 was also open concurrently with the District 106 openings throughout the entire season. The following additional fishing times were permitted in District 108: a 2-day mid-week opening in statistical week 25 (June 16 to June 22); a 3.5-day mid-week opening in statistical week 26 (June 23 to June 29); and 2-day mid-week openings in statistical weeks 29 and 30 (July 14 to July 27). During the time period when mid-week openings were allowed the SMM indicated a U.S. TAC of between 83,151 and 219,430 sockeye salmon based on the river estimate of total run size. The management approach of providing extra time in District 108 and a small portion of District 106 was used to regulate the harvest of the local island sockeye salmon stocks in District 106 while maximizing the harvest of Stikine sockeye salmon in District 108. Effort was high and, while sockeye salmon catches were strong in Sumner Strait, the catches throughout District 106 were not strong enough to warrant additional time in all of District 106 during the early weeks.

Area restrictions were used around the mouth of the Stikine River for the first two statistical weeks (weeks 24 and 25) and in portions of Frederick Sound each week during the sockeye and pink salmon fisheries to protect adult Chinook salmon returning to the Stikine River. During July and the first week of August the closure line for District 108 was moved in to the Point Rothsay to Indian Point line to avoid areas of known high Chinook salmon abundance.

The management emphasis changed from sockeye salmon to pink salmon during statistical week 34 (August 18 to 24). This season there were 188,035 and 37,651 pink salmon harvested in District 106 and 108, respectively (Appendices A. 5 and A.7). The District 106 catch is $55 \%$ of the average of 343,501 pink salmon (Appendix B.5), while District 108 catch is $57 \%$ above the respective average of 24,038 pink salmon (Appendix B.7). Pink salmon catches in both districts are not always a true reflection of the pink salmon abundance in the area because the low pink salmon price, along with the high abundance of sockeye and coho salmon, affect the fishing patterns and methods A three-day fishing period was allowed during the week of pink salmon management in both districts. The pink salmon escapements throughout Districts 106 and 108 were above average.

Figure 2. Average catches and fishing efforts compared with 1996 for the Alaska Districts 106 and 108 and for the Canadian inriver fisheries in the Stikine River.

Coho salmon management in both the District 106 and 108 gillnet fisheries usually commences during late August or early September. During statistical week 35 (August 25 to August 31) the management emphasis changed from pink to coho salmon. Early gillnet catches of coho salmon were above or at average levels and the inseason outside troll fishery indicated an above average run. Prior to the change to coho salmon management, the sockeye and pink salmon fisheries harvested approximately $63 \%$ of the total District 106 coho salmon catch and approximately $33 \%$ of the total District 108 coho salmon catch. Both districts were open for three days during statistical weeks 35 and 36 (August 25 to September 7), two days during statistical weeks 37 and 39 (September 8 to 28). The total coho salmon catch each week was about average while the effort was above average and the CPUE was generally near or below average. Normally the percentage of hatchery coho salmon starts to increase by mid-August and by the end of season makes up a high percentage of the weekly catch. This season the hatchery contribution followed the normal pattern throughout the season. The District 106 coho salmon catch of 223,640 is the fourth highest on record and is $34 \%$ above the 1986-1995 average of 166,534 fish (Appendices A. 5 and B.5). The District 108 coho salmon catch of 19,059 is the eighth highest on record and is $40 \%$ higher than the $1986-1995$ average of 13,597 fish (Appendices A. 7 and B.7). Fishing effort in both districts was higher than normal. The Alaska hatchery coho salmon contribution to the District 106 fishery is estimated at 54,621 fish (24\%) (Appendix A.5) and the contribution to the District 108 fishery is estimated at 1,271 fish (7\%) (Appendix A.7).

During the 1996 season, the gillnet fishery in District 106 was open for a total of 46 days (Appendix A.5), and in District 108 for 56.5 days (Appendix A.7). These were above the Districts 106 and 108 1986-1995 averages of 33.1 and 36.2 days, respectively (Appendices B. 5 and B.7). District 106 fishing effort in numbers of vessels was near the average for the first four statistical weeks (weeks 25 to 28), $14 \%$ to $48 \%$ above average for the following eight statistical weeks (weeks 29 to 36), and below average for the last three statistical weeks (weeks 37 to 39) of the season. Because of the extremely strong sockeye salmon and good coho salmon runs, the fishing effort in District 106 was 55\% higher than the 1986-95 average (Figure 2, Appendix B.5). The District 108 weekly fishing pressure was about average during the regular openings but increased to double the average during the mid-week extensions. After the mid-week extensions were suspended the effort remained near average. The greatest number of boat-days in District 106 (649) was in statistical week 28 while the greatest number of boats fishing (162) occurred in statistical week 31, which is the end of July. The effort of 5,290 boat-days in District 106 was $55 \%$ higher than the 1986-1995 average of 3,420 boat-days. The District 108 effort was higher than average due to the extended fishing time allowed to harvest the large run of Stikine River sockeye salmon. The 1,696 boat-days fished in District 108 was $98 \%$ higher than the 1986-1995 average of 857 boat-days (Appendix B.7). Most of the boats fishing during the mid-week openings in District 108 did not fish the entire opening so the effort in boat-days was adjusted to better reflect the time actually fished during these openings. For this reason the boat-days given in Appendix B. 7 are less than that obtained by multiplying the number of permits fished by the number of days the fishery was open.

Figure 3. Sockeye salmon catches for the Alaska District 106 and 108 and the combined Canadian fisheries in the Stikine River and Stikine sockeye salmon escapements, 1979-1996.

While there was some effort in the U.S. personal use fishery in the lower Stikine River, there was no reported catch. Based on CWT sampling in Wrangell and the creel survey in Petersburg, an estimated 2,460 Chinook salmon were taken by sport anglers from May 7 to July 14, 1996, in these two locations. An estimated 903 (37\%) of these were Alaska hatchery Chinook salmon.

## CANADIAN FISHERIES

Catches from the combined Canadian commercial and Aboriginal gillnet fisheries in the Stikine River in 1996 included: 2,471 large Chinook, 421 jack Chinook, 74,281 sockeye, 1,404 coho, 25 pink, and 232 chum, and 183 steelhead salmon (Figure 4, Appendix A.9, A.11, A. 12 and B.17). The sockeye salmon catch was the highest on record and was 2.7 times the 1986-1995 average of 27,520 sockeye salmon. The catch of large Chinook salmon was $24 \%$ above average and the catch of steelhead salmon was $13 \%$ above average whereas, the catches of jack Chinook, pink and chum salmon were all below average. In addition to these catches, 12,955 sockeye salmon were taken in an ESSR harvest at Tahltan Lake (Appendix B.18).

A test fishery was conducted again in the lower Stikine River, just upstream from the Canada/U.S. border, to determine migratory timing and stock composition of the sockeye salmon run for use in the postseason estimations of the inriver sockeye and coho salmon run sizes. The weekly test fishery sockeye salmon CPUE and stock ID results were also used inseason in the SMM to forecast the total run size. Test fishery catches included: 298 large Chinook, 76 jack Chinook, 1,312 sockeye, 55 coho, 4 pink, 55 chum, and 11 steelhead salmon (Appendices A. 14 and B.19).

## Lower Stikine Commercial Fishery

Canadian commercial fishers in the lower Stikine harvested 1,708 large Chinook, 221 jack Chinook, 66,262 sockeye, 1,402 coho, 25 pink, 229 chum, and 153 steelhead salmon in 1996 (Appendix A.9). The sockeye salmon catch exceeded the previous record of 45,622 sockeye salmon in 1995, and was $296 \%$ above the 1986-1995 average of 22,417 sockeye salmon (Appendix B.12). The catch of large Chinook salmon was $88 \%$ above the previous ten-year average of 1,026 Chinook salmon, whereas, the catch of jack Chinook salmon and all other salmon species was below respective 1986-1995 averages. A very strong sockeye salmon run combined with relatively low fishing effort resulted in the fishery being open almost continuously from July 07 through August 08. The exception to this was a three-hour closure at the drift site near the Canada/U.S. border in the morning of day 5, 6 and 7 each week to allow the test fishery to operate.
The fishery commenced at noon on Sunday, June 23 (statistical week 26), for a scheduled opening of four days. Record high daily sockeye salmon catches and catch per unit of effort measured in sockeye/fisher/day (CPUE), combined with light effort, i.e. a maximum of eight fishers present, and a shortfall in catch relative to the weekly guideline harvest prompted a three day extension. Weekly guideline harvests, based on current forecasts of the total allowable catch apportioned by average run timing and domestic and international allocation agreements, were developed each week to guide management decisions. The weekly catch of 6,078 sockeye salmon, which was close to the weekly guideline of 6,040 sockeye salmon, was a record for statistical week 26 and was approximately 5.5 times the previous ten-year average catch for this week. The sockeye salmon CPUE was also record high and was $392 \%$ above average. Run
forecasts derived from fishery performance data from this week ranged from 232,000 sockeye salmon (from test fishery data) to 310,000 sockeye salmon (from inriver commercial CPUE data), these forecasts were above average but below the preseason forecast of approximately 329,000 sockeye salmon.
In statistical week 27, the fishery was scheduled to open for five days commencing Sunday, June 30. Test fishery catches of 2-3 sockeye/drift were well above average just prior to the opening indicating that the forecast based on test fishery data would likely increase this week. Record high sockeye salmon catches and CPUE continued to prevail in the fishery over the first four days. Fishing time was extended by twenty-four hours but was not extended further due to the cumulative catch being above the guideline for the week and the need for some caution since the test fishery based forecast was somewhat lower than expected. The catch of 17,796 sockeye salmon in statistical week 27, more than 8 times the average catch for this week, was the highest weekly catch ever recorded in the fishery; the previous record was a catch of 10,322 sockeye salmon catch in statistical week 28 in 1995. It was also noted in this week that the weight of the sockeye salmon was approximately 0.5 kg heavier than normal with some fish weighing in excess of 5.4 kg .

The sockeye salmon run strength remained high over the next three weeks resulting in record/near record weekly catches and CPUE. Sockeye salmon run forecasts ranged from 310,000 sockeye salmon (test fishery based forecast in statistical week 28) to 493,000 sockeye salmon (statistical week 29 forecast based on inriver commercial CPUE). Decisions to increase the fishing times in statistical weeks 28 through 30 to seven days, were made based on the record run forecasts, above average CPUE and the status of the cumulative catch relative to weekly guideline levels. In spite of the continuous fishing effort, the cumulative catch fell progressively further behind as the season progressed.

After statistical week 30, according to the commercial CPUE the weekly sockeye salmon run strength appeared to return to about average levels. Weekly fishing times were reduced from seven days in statistical week 31 to five days in each of statistical weeks 32 and 33 in response to lower sockeye salmon abundance. Sockeye salmon run forecasts continued to be at record levels although they steadily declined from statistical week 31 through the end of the sockeye salmon season. The final inseason sockeye salmon forecast indicated a Canadian TAC of 111,000 to 141,000 sockeye salmon. Accounting for the combined Aboriginal and commercial harvest in the upper river, i.e. approximately 8,000 sockeye salmon, the final inseason estimates translated into a lower river target 103,000 to 133,000 sockeye salmon.

Figure 4. Catches of Chinook, coho, pink, and chum salmon in the combined Canadian fisheries in the Stikine River, 1979-1996.

When comparing the sockeye salmon CPUE for statistical weeks in 1996 with those of other years, the early portion of the sockeye salmon run timing appeared to be about 1-2 weeks earlier than normal. The peak CPUE occurred in statistical week 27 when normally it occurs in statistical week 29. The timing of the latter half of the run appeared to be normal. Tahltan Lake sockeye salmon dominated the catch through July 20 (statistical week 29); thereafter, the mainstem sockeye salmon stock component made up the majority of the sockeye salmon catch. Of the total lower river sockeye salmon catch, 42,938 sockeye salmon were of Tahltan/Tuya lake origin ( $65 \%$ of the catch) and 23,324 originated from the Mainstem Stikine sockeye salmon conglomerate (Appendix A.10).
It was evident by mid-July that the number of sockeye reaching the Tahltan Lake weir surplus would exceed escapement requirements. This prompted the issuance of an "Excess Salmon To Spawning Requirements License (ESSR) which permitted the terminal harvest of sockeye salmon at Tahltan Lake. A total of 12,955 sockeye salmon was harvested under the ESSR (Appendix B.18).
From the middle of August through the end of the season (September 21), only 1-2 fishers remained in the fishery. Management emphasis usually switches to coho salmon as sockeye salmon abundance drops off towards the end of August. However, due to poor market conditions, there was little effort towards targeting coho salmon in 1996. The fishery was open for three to seven days per week after the end of August and generally the coho salmon CPUE was below average. The peak coho salmon catch of the season occurred in statistical week 36.
Eighteen licensed fishers participated in the fishery throughout the season with an average of six licenses active each week throughout the season, about $60 \%$ the usual number of fishers. The total effort in terms of boat-days was 439, $27 \%$ above the 1986-1995 average of 346 boat-days (Appendix B.12). The above average effort level in 1996 was primarily due the record sockeye salmon run which resulted in extended fishing periods throughout July and early August. As in 1995, each fisher was allowed the use of two gillnets of which one could be a drift net. This was the second year that additional gear was permitted throughout the entire season. In 1994, the second piece of fishing gear was allowed only after the first 48 hours of fishing in each week. A delayed opening to June 23 and a maximum mesh size restriction of 150 mm through mid-July was implemented to reduce the incidental catch of Chinook salmon.

## Upper Stikine Commercial Fishery

A small commercial fishery has existed near Telegraph Creek on the upper Stikine River since 1975. The catch recorded in 1996 included: 41 large Chinook salmon, which was approximately one half the 1986 to 1995 average of 79 large fish, 44 jack Chinook, and 1,101 sockeye salmon which was $3 \%$ above average (Appendices A. 11 and B.14). The fishing effort was above average with one to four fishers fishing up to seven days per week. A total of 59 days was fished and the total effort amounted to 75 boats-days. For comparison, the previous ten-year average fishing time was 15 days with an average effort of 30 boat-days.
The additional time fished during the season was the result of the excellent run of sockeye salmon.

## Aboriginal Fishery

The Stikine Aboriginal fishery, centered around Telegraph Creek, harvested 722 large Chinook, 156 jack Chinook, 6,918 sockeye, 2 coho, 3 chum, and 30 steelhead salmon (Appendix A 12).

The catch of sockeye salmon was $72 \%$ above the 1986-1995 average of 4,031 sockeye salmon, whereas the harvest of large Chinook salmon was $19 \%$ below the ten-year average of 896 Chinook salmon (Appendix B 15). As in past years, fishing times were not restricted in this fishery.

## EsCAPEMENT

## Sockeye Salmon

A total of 52,500 sockeye salmon was counted through the Tahltan Lake weir in 1996, which was $72 \%$ above the 1986-1995 average of 30,510 sockeye salmon (Appendix B.22). Analysis of thermal marks from otoliths sampled from Tahltan Lake indicated that an estimated 5,914 fish (11.3\%) originated from the enhancement program. Of the total number of fish enumerated through the weir, 2,181 females and 2,156 males were collected for hatchery broodstock. In addition to the broodstock collection, 12,955 sockeye salmon were harvested under the ESSR license, leaving a spawning escapement of 35,143 fish (Appendix B. 18 and B.22). This exceeded the escapement range of 18,000 to 30,000 fish.

The spawning escapements for the Mainstem and Tuya stock groups are estimated indirectly by computing the ratio of Tahltan to Mainstem and Tuya components in the total inriver sockeye salmon run. Stock identification data are collected in the lower river commercial and test fisheries. The ratios of Tahltan to Mainstem and Tahltan to Tuya are applied to the estimated inriver Tahltan run size to develop an estimate of the total inriver sockeye salmon run. The escapements are estimated by subtracting the catches of Mainstem and Tuya sockeye salmon in the Canadian fisheries. The postseason escapement estimates are 45,203 Mainstem fish and 10,612 Tuya fish based on egg diameter and thermal mark incidence from inriver fisheries and the inriver commercial fishery CPUE data to give run timing. This estimate was above the goal for the Mainstem stock and is $21 \%$ above the 1986-1995 average of 37,457.
Aerial surveys of Mainstem sockeye salmon escapement index areas indicated above average numbers of spawners in 1996 (Appendix B.23). The 1996 cumulative index count of 1,053 sockeye salmon was $14 \%$ above of the 1986-1995 average of 920 fish. The 1996 survey conditions were fair to good. These surveys do not include all spawning populations; the index represents the combined counts from up to seven spawning areas.

## Chinook Salmon

This was the twelfth consecutive year of the operation of an adult Chinook salmon enumeration weir on the Little Tahltan River. The 1996 count of 4,821 large Chinook salmon was $90 \%$ of the 1986-1995 average of 5,384 large fish (Appendix B.25). The 1996 escapement was below the Little Tahltan escapement goal of 5,300 Chinook salmon. The count of jack Chinook salmon was 22, well below the 1986-1995 average of 269 fish. Daily counts from the 1996 program are presented in Appendix A.18.

Figure 5. Chinook salmon weir counts and index escapement estimates for major spawning areas and for the entire Stikine River, 1979-1996.

Results from aerial and foot surveys conducted on Stikine River tributaries indicated a below average Chinook salmon escapement in 1996. Survey counts for Little Tahltan River were 1,920 Chinook salmon compared to the 1986-1995 average of 2,491 fish; for Beatty Creek, 218 Chinook salmon compared to the average of 337 fish; for Tahltan River, 772 Chinook salmon compared to the average of 2,074 fish; and for Andrew Creek, 332 Chinook salmon compared to the average of 640 fish (Figure 5, Appendix B.26).

## Coho Salmon

The lower Stikine River test fishery ended on statistical week 35 (week ending August 31), which precluded complete coverage of the coho salmon run. From historical test fishery catch records, 1986 to 1990, approximately $48 \%$ of the coho salmon run migrates through the lower river by statistical week 35 . The cumulative coho salmon test fishery CPUE was expanded accordingly (2.30/0.48) and the resultant projected CPUE (4.78) was calculated to be $32.5 \%$ of the total 14.72 cumulative sockeye salmon CPUE. The inriver coho salmon run then was estimated to be $20.8 \%$ of the inriver sockeye salmon run size of 189,559 fish, or 61,030 coho salmon. Subtracting the combined inriver catch of 1,402 coho salmon in the Canadian commercial fishery and 55 coho salmon taken in the inriver test fishery gives an estimated total coho salmon escapement of 59,573 fish, which is above the interim escapement goal range of 30,000 to 50,000 coho salmon. Aerial surveys of six coho salmon spawning index sites indicated above average spawning escapement for three of the six streams surveyed (Appendix B.27).

## Sockeye Salmon Run Reconstruction

The postseason estimate of the Stikine sockeye salmon run size is 372,294 fish, of which 242,859 are of Tahltan Lake origin (wild + enhanced), 38,841 are from Tuya Lake, and 90,593 are Mainstem (Table 2). These estimates are based postseason analysis of scale patterns and otolith recovery and analysis for U.S. Districts 106 and 108 catches; egg-diameter and otolith stockcomposition estimates for inriver catches; Canadian commercial, aboriginal, ESSR, and test fishery catches; and escapement data. A Stikine run size of this magnitude is 2.6 times the 19861995 average run size of 141,426 sockeye salmon, and exceeds the previous high of 280,730 in 1993 by 33\%. The 1986-1995 average run sizes of Tahltan and Mainstem fish are 69,541 and 71,726 sockeye salmon, respectively (Appendix B.28).
The postseason estimate of the run size is slightly above the preseason forecasts of 329,000 (Canadian) and 341,000 (U.S.) fish. The Canadian forecast was composed of the following components: 197,000 wild Tahltan Lake sockeye salmon; 26,000 enhanced Tahltan Lake sockeye salmon; 38,000 enhanced Tuya Lake sockeye salmon; and 68,000 Mainstem/Tuya sockeye salmon. The U.S. used the same components in their forecast with the exception of the wild Tahltan Lake component where the U.S. forecast 209,000. The Tahltan components of the run (wild and enhanced) were estimated by averaging smolt-based and sibling-based estimates. The combined sibling-based forecasts of wild and enhanced Tahltan runs, 199,900 sockeye salmon was closest ( $11 \%$ above) to the postseason estimate; the combined smolt-based forecasts totaled 245,400 sockeye salmon $36 \%$ above the postseason estimate. Of the different components, the Tuya forecast was the closest to the estimate, only $8 \%$ low. For the Mainstem sockeye salmon component, the preseason sibling forecast of 68,000 sockeye salmon was $47 \%$ of the postseason Mainstem run size estimate of 145,295 fish and had the greatest difference in numbers of fish (over 77,000).

${ }^{a}$ Escapement into terminal and spawning areas from traditional fisheries.
${ }^{\mathrm{b}}$ Catch allowed in terminal areas under the Excess Salmon to Spawning Requirement license.
${ }^{\text {c }}$ Planted fish returning to the Tuya system are not able to access Tuya Lake due to velocity barriers.
${ }^{\mathrm{d}}$ The number of Tuya fish that should pass through the traditional fisheries in order to avoid overexploitation of the Tahltan stock.
${ }^{\mathrm{e}}$ Includes traditional, ESSR, and test fishery catches.
${ }^{\mathrm{f}}$ Does not include ESSR catches.
${ }^{\mathrm{g}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

Based on weekly random sampling of otoliths collected in Districts 106 and 108 commercial fisheries, the contribution from Stikine sockeye salmon fry plants consisted of 16,567 sockeye salmon of Tahltan Lake origin, and 19,442 sockeye salmon of Tuya Lake origin. Estimates of contribution from fry plants to the Canadian fisheries are approximately 6,496 sockeye salmon of Tahltan Lake origin, and 8,926 sockeye salmon of Tuya Lake origin.

For the Canadian analysis, the SMM appeared to overestimate the run size this season. In statistical weeks 28 through 31 the SMM estimated well a run well over 400,000, in statistical weeks 32 through 35 the estimate steadily declined and the final inseason forecast of the run size derived from the SMM ( 336,705 sockeye salmon) was just $8 \%$ below the postseason estimate of the total run ( 372,294 sockeye salmon). For the U.S. analysis, a similar pattern occurred with the final inseason forecast of 360,476 sockeye salmon nominally equal to the postseason estimate. The SMM will be reviewed and updated to include 1996 data in making predictions for the 1997 season.

## TAKU RIVER

Taku River salmon are harvested in the U.S. gillnet fishery in the Alaskan District 111, in northern Southeast Alaska seine and troll fisheries, and in the Juneau area sport fishery and inriver personal use fishery (Figure 6). Canadian fisheries for Taku River salmon include a commercial gillnet fishery located in the river near the U.S./Canada border, a sport fishery, and an Aboriginal fishery.

## Harvest Regulations

As with Stikine River issues, efforts to re-negotiate harvest shares of Taku River salmon during the Pacific Salmon Commission and government-to-government negotiations were not successful. As a result, the Parties unilaterally developed the following management plans for the 1996 season:

1) As in 1995, the Canadian management plan did not numerically constrain Canadian harvests of sockeye and coho salmon since provisions to do so had expired in 1992. The basic objective of the management plan for each species was to manage according to the conservation requirements, i.e. escapement goals, for each species. In agreement with unexpired portions of Annex IV, the plan did not permit targeting on Chinook salmon in the Taku River since both Parties had previously agreed to rebuild Chinook salmon by 1995. The joint assessment of the status of rebuilding efforts has not yet been completed.
2) The U.S. management plan reflected the provisions that were in effect for 1993, namely to provide for Canadian harvests of $18 \%$ of the TAC of Taku River sockeye and 3,000 coho salmon. As with the Canadian management plan, targeting on Chinook salmon was not permitted.

## U.S. Fisheries

The District 111 drift gillnet fishery was open for a total of 46 days from June 16 through September 16, 1996 (Appendix C.1). Fishing effort, as measured by the total number of boats delivering fish each week times the number of days open to fishing, totaled 3,229 boat-days, 5\% below the previous 10 -year average. Fishing time and effort were above average during the summer fishing season but below average in the fall. Processors imposed chum salmon catch limits on fishers from early July through mid-August because the region-wide abundance of
summer chum salmon exceeded their processing capacities. The catch limits had a dramatic effect on the distribution of effort within the district.

The 1996 commercial salmon harvests in the District 111 fishery totaled 2,659 Chinook, 199,014 sockeye, 33,633 coho, 12,660 pink, 354,067 chum, and 240 steelhead salmon (Appendix C.1). The sockeye and chum salmon catches were the largest in the history of the fishery, while catches of Chinook, coho and pink salmon were below average (Appendix D.1). Enhanced stocks contributed significantly to the harvests of all species except pink salmon. The Chinook salmon harvest of 2,659 fish was $21 \%$ below the 1986 to 1995 average. Alaskan hatchery fish contributed approximately $20 \%$ ( 533 fish) of the harvest (CWT estimate). The only management action taken for Chinook salmon conservation was during the first statistical week of the season when Taku Inlet was closed north of the latitude of Jaw Point.

The sockeye salmon harvest of 199,014 fish was $96 \%$ above the previous 10-year average of 101,418 , and exceeded the previous record harvest by $14 \%$. Sockeye salmon catch and CPUE were above average throughout the summer season. The weekly harvests of 51,914 and 43,426 fish between July 14 and July 25 were the highest recorded in the history of the fishery. The average weight of sockeye salmon taken in the fishery was 7.25 pounds, above the previous 10year average of 6.7 pounds and the heaviest average weight since 1982.

Fishing effort during the summer season concentrated more heavily in Taku Inlet than in recent years, and $94 \%$ of the sockeye salmon harvest (187,207 fish) occurred in the inlet (Appendix C. 2 and C.3). Fishers chose to avoid outer portions of Taku Inlet and Stephens Passage because chum salmon abundance in these areas was so high they would quickly reach their catch limit, thereby restricting their ability to harvest the strong run of higher valued Taku River sockeye salmon. Fishing time in Taku Inlet varied from three to four days per week until the last week of July, when time was reduced to two days to increase escapement of late run stocks into the Taku River. Fishing time was then increased to three and four days per week, respectively, for the final two weeks of the summer fishing season as escapement levels increased.

Port Snettisham was closed through August to continue rebuilding Crescent and Speel lake stocks, except for a short two-day opening in inner Port Snettisham (Gilbert Bay) allowed in late July to harvest surplus Crescent Lake sockeye salmon. Runs of these stocks were quite strong but were not heavily harvested due to the lack of effort in Stephens Passage.

Figure 6. The Taku River and principal U.S. and Canadian fishing areas.

Table 3. Taku and Snettisham sockeye salmon run reconstruction, 1996. Estimates do not include Taku spawning escapements below the U.S./Canada border or Taku sockeye salmon harvested in marine areas outside District 111.

${ }^{\text {a }}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

Several other fisheries in the Juneau area harvested transboundary river stocks in 1996. Estimates of the harvest in the U.S. personal use fishery in the lower Taku River are 87 Chinook, 2,977 sockeye, 163 coho, 285 pink, and 15 chum salmon (Appendix D.4). The spring Juneauarea sport fishery harvested an estimated 4,900 Chinook salmon. An estimated 3,960 (80\%) were mature wild spawners and an additional 760 (15\%) were of Alaskan hatchery origin (CWT estimate). A number of stocks are thought to contribute to the fishery, including those from the Taku, Chilkat, and King Salmon rivers, and local hatchery stocks, but the major contributor of mature fish is believed to be the Taku River. The July Hawk Inlet shoreline purse seine fishery north of Point Marsden in Chatham Strait was not opened this year due to very poor runs of pink salmon to many Juneau area streams; this fishery, when open, harvests some salmon of Taku River origin. Taku River coho salmon are also harvest in the Southeast Alaska troll and recreational fisheries.

## Canadian Fisheries

Taku River commercial fishers harvested 41,665 sockeye, 5,028 coho, 3,331 large Chinook, and 144 jack Chinook salmon (fish less than 2.27 kg ), and 98 steelhead salmon in 1996 (Appendix C.4). The sockeye salmon catch was the highest on record and was $82 \%$ above the 1986-1995 average of 22,911 sockeye salmon (Figure 7, Appendix D.5). The catch of large Chinook salmon was also a record and was more than three times the previous ten-year average of 1,099 Chinook salmon. Contrasting this, the catch of jack Chinook salmon was $25 \%$ below average and the catch of coho salmon was $9 \%$ below the previous ten-year average of 5,527 fish. The fishery was open for a total of 65 days, well above the previous ten-year average of 32 days and the seasonal fishing effort was 415 boat-days, $36 \%$ above the 1986-1995 average of 304 boat-days. The above average fishing time and effort was reflective of the existence of a fall fishery that in many previous years had been curtailed by Treaty restrictions.

In addition to the commercial catches, 360 sockeye, 24 coho and 63 Chinook salmon were harvested in the Aboriginal fishery in 1996 (Appendix D.7).
The Taku River Tlingit First Nation, in cooperation with DFO, conducted a creel census on the Nakina River in 1996. Information from the creel census was expanded to provide the following catch estimate: approximately 800-900 Chinook salmon were landed of which an estimated $90 \%$ were released.

The Canadian preseason forecast was for a run of approximately 219,000 sockeye salmon that was the average of a sibling -based forecast of 227,000 sockeye salmon, and a forecast of 211,000 sockeye salmon based on stock-recruitment data. The point estimate was close to 19861995 ten-year average run size of approximately 213,301 sockeye salmon (Canadian estimate). The preseason forecast was used to guide weekly management actions for the first three weeks of the season; thereafter, inseason forecasts based on the joint Canada/U.S mark-recapture program at Canyon Island were used (Table 4).

The commercial fishery commenced at noon on Sunday, June 16 (statistical week 25) for a scheduled opening of two days. The sockeye salmon CPUE of 56 sockeye/fisher/day was $68 \%$ above the 10 -year average for this week. However, low water levels, which may have increased catchability, and concerns about potential effects on increasing incidental Chinook salmon catches lead to the decision to close the fishery after two days. Fishing time was scheduled for three days in the following week from June 23-26 in response to the strong initial sockeye salmon showing. Although the commercial fishery CPUE after the first 2.8 days of statistical week 26 was below average, the fishing time was extended by 24 hours due to record high cumulative sockeye salmon catches in the Canyon Island fish wheels.

When fish wheel catches dropped to below average values in statistical week 27, the fishery, which continued to show below average CPUE, was restricted to three days of fishing, June 30 to July 03. The first inseason forecast was made at the end of this opening and ranged from 171,000 to 338,000 sockeye salmon. The wide range in the forecast was the result of two different timing scenarios assumed: the lower end of the range was the forecast based on expanding the current mark-recapture estimate by average run timing; whereas, the upper end of range represented the forecast based on an assumed one week delay in run timing. Associated with the run forecast was a total spawning escapement projection that ranged from 83,000 to 164,000 sockeye salmon (Table 4). This was above the goal of 71,000 to 80,000 sockeye salmon.

The fishery in statistical week 28 was also scheduled for three days, from July 7-10. Although commercial catches were below average for the first day, Canyon Island fish wheel catches showed a marked improvement indicating the beginning of a pulse of fish early in the week. Catches in the District 111 gillnet fishery in the previous week had improved and the CPUE was $35 \%-40 \%$ above average; to this point in the season, the CPUE in District 111 was indicating an above average run. On day three of statistical week 28, the Canadian commercial CPUE rose to above average values of approximately 100 sockeye/fisher/day. Based on increasing fishery performance and indications of a strong run outside of the river, the fishery was extended 24 hours.

Table 4. Canadian inseason forecasts of total run size, TAC, and Spawning Escapement of Taku sockeye salmon, 1996.

| Statistical | Total Run |  |  | TAC |  |  | Escapement |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Week | from | to |  | from | to |  | from | to |

| 26 | 211,000 | 227,000 |  | 136,000 | 152,000 |  |  |  |
| 27 | 211,000 | 227,000 |  | 136,000 | 152,000 |  |  |  |
| 28 | 171,146 | 337,763 |  | 96,146 | 262,763 |  | 83,118 | 164,036 |
| 29 | 195,662 | 315,111 |  | 120,662 | 240,111 |  | 79,500 | 128,034 |
| 30 | 227,214 | 318,795 |  | 152,214 | 243,795 |  | 67,591 | 94,834 |
| 31 | 277,538 | 366,524 |  | 202,538 | 291,524 |  | 56,935 | 75,190 |
| 32 | 324,512 | 393,606 |  | 249,512 | 318,606 |  | 71,731 | 87,003 |
| 33 | 351,105 | 417,724 |  | 276,105 | 342,724 |  | 105,089 | 125,028 |
| 34 | 325,289 | 361,838 |  | 250,289 | 286,838 |  | 91,748 | 102,056 |

The total run forecast produced from statistical week 28 inputs increased to a range of 196,000 to 315,000 sockeye salmon although the projected season escapement dropped to the 79,000 to 128,000 sockeye salmon range; the escapement projection was still at, or above, goal levels (Table 4). Above average CPUE in the early part of the opening and strong outside catches in the previous week in District 111 (over 30,000 sockeye salmon and CPUE 85\%-90\% above average), lead to an 24 hour extension over the scheduled three day opening in statistical week 29.

The catch in District 111 was a record high in statistical week 29 (over 50,000 sockeye salmon, CPUE $120 \%$ above average) indicating the likelihood of strong inriver run strength the following week. This appeared to hold true; Canyon Island fish wheel catches in the early part of statistical week 30 were the highest to this point in the season and the CPUE in the Canadian fishery after the first 2.8 days of fishing was 210 sockeye/fisher/day compared to an average for this statistical week of 111 sockeye/fisher/day. These factors lead to a twenty-four hour extension to the scheduled three-day opening. The weekly catch totaled 8,284 sockeye salmon, the second highest catch for this week on record and the CPUE of 176 sockeye/fisher/day was also the second highest on record for this week.
The forecast developed for statistical week 30 (from statistical week 29 inputs) had increased marginally ranging from 227,000 to 319,000 sockeye salmon, however, this was the first week in
the season when the lower end of the projected escapement range, 67,600-94,800 sockeye salmon forecast in statistical week 30, fell below the lower end of the escapement goal range, i.e. 71,000 sockeye salmon (Table 4). This trend continued in statistical week 31 with the run forecast increasing to 277,000 to 367,000 sockeye salmon which was buoyed primarily by record catches in District 111 (125,000 sockeye salmon caught from statistical weeks 28 through 30) but the escapement projection declining to the 57,000 to 75,000 sockeye salmon range (Table 4).

The fishery for statistical week 31 was scheduled for three days from July 28-31. During the first 2 days of the opening, it soon became apparent that the peak of the run was near. Canyon Island fish wheel catches increased to more than 300 sockeye/day and the CPUE in the commercial fishery was at an all time record level (>260 sockeye/fisher/day). In spite of the strong showing of sockeye salmon, the fishery was closed after three days due to concerns over the declining escapement projections that existed going into this week. The weekly catch of 9,045 sockeye salmon was the highest weekly catch for any week on record and was approximately 2.5 times the average catch for this week.
The run forecast range after statistical week 31 increased to 325,000 to 394,000 sockeye salmon and the escapement projection improved to the 72,000 to 87,000 sockeye salmon range (Table 4). A three-day fishery was posted for statistical week 32 (August 4-7). Catch rates remained well above average during the first couple of days of the opening and the CPUE was about 105\% above average; these factors combined with the improved escapement outlook and knowledge that the CPUE in the District 111 was still well above average, prompted a twenty-four hour extension. The catch of 8,360 sockeye salmon ( $183 \%$ above average) and CPUE of 190 sockeye/fisher/day ( $112 \%$ above average), established new record values for statistical week 32. Mid-week mark-recapture estimates indicated that the spawning escapement had surpassed the upper end of the escapement goal range; the cumulative spawning escapement was estimated to be approximately 84,000 sockeye salmon.

Weekly fishing times decreased to three days in statistical week 33, then to two days in statistical week 34 as the sockeye salmon numbers dropped off and the commercial sockeye salmon CPUE decreased to roughly average values. With the end of the sockeye salmon season in sight and indications that coho salmon prices would be unattractive, effort levels also fell from an average of 11 fishers/day in statistical week 32, to 5 fishers/day in statistical week 34.

The final inseason sockeye salmon forecast indicated a total run in the 325,000 to 362,000 sockeye salmon range and a spawning escapement in the range of 92,000 to 102,000 sockeye salmon. The postseason run estimate is 324,835 sockeye salmon and the escapement is estimated to be 92,626 sockeye salmon. The Canadian catch of 42,025 sockeye salmon represented approximately $16.6 \%$ to $17.2 \%$ of the TAC (Table 3).

Fishing time was increased to four days in statistical weeks 35 (August 25-29) and 36 (September 1-5) to target coho salmon. Although the peak coho salmon catch of the season occurred in statistical week 35,weekly catches and effort were below average. Fishing time was reduced to three days in statistical week 37 but then opened to seven days/week for the remainder of the season with only one fisher fishing two licenses left on the river. Through the end of August, the cumulative coho salmon CPUE was slightly above average, 195 coho/fisher/day compared to the 1988-1995 average cumulative CPUE of 187 coho/fisher/day. However, weekly coho salmon CPUE's were well below average for the rest of the season. The
total season catch of coho salmon was 5,028 fish, $9 \%$ below the previous ten-year average (Appendix D.5).

As in recent years, both set and drift gillnetting techniques were utilized with the majority of the catch taken in drift gill nets. Mesh sizes were restricted to less than 150 m through mid-July to minimize the incidental catch of Chinook salmon. One fish wheel was in operation for a brief period of time.

## EsCAPEMENT

## Sockeye Salmon

Spawning escapement of sockeye salmon in the Canadian portion of the Taku River drainage is estimated from the joint Canada/U.S. mark-recapture program. Counting weirs operated by DFO at Little Trapper and Tatsamenie lakes provide information on the distribution and abundance of discrete spawning stocks within the watershed. Additional sockeye salmon enumeration programs were conducted at Kuthai Lake and the Nahlin River by the Taku River Tlingit First Nation (TRTFN) in 1996.

A mark-recapture program has been operated annually from 1984 to 1996 to estimate the aboveborder inriver run size (i.e., border escapement); spawning escapement may then be estimated by subtracting the inriver catch. The 1996 estimate of above-border run is 134,651 sockeye salmon and the spawning escapement, 92,626 fish (Appendix C.7). This spawning escapement is $12 \%$ below the 1984-1995 average of 105,729 fish, but is $16 \%$ higher than the upper end of the interim escapement goal range of 71,000 to 80,000 sockeye salmon (Figure 8).

The escapement through the Little Trapper Lake weir was 5,483 sockeye salmon, $42 \%$ of the 1983-1995 average of 13,123 fish (Appendix D.10).
Prior to 1995, weir counts for the Tatsamenie system were made at Little Tatsamenie Lake and included fish which spawn between Little Tatsamenie and Tatsamenie lakes as well as fish which spawn in Tatsamenie Lake and its outlet stream. In 1995 the weir was moved upstream to Tatsamenie Lake. The escapement count through the Tatsamenie Lake weir in 1996 was 9,381 sockeye salmon (Appendix C.8). To be comparable with earlier spawning estimates, it needed to be expanded to represent the entire Tatsamenie system. In addition, the weir was installed late in relation to the run timing so the weir count was first expanded to include the missed portion of the upper Tatsamenie run (approximately 1,000 fish). In 1994 weirs were operated at both Little Tatsamenie and Tatsamenie lakes; approximately $40 \%$ of the fish counted at the Little Tatsamenie weir did not migrate as far as the upper weir site at Tatsamenie Lake. Since this was from only one year and seemed high to the biologist working on the system, the upper Tatsamenie estimate was expanded by $1 / 0.8$ rather than $1 / 0.6$. The resulting escapement to the entire Tatsamenie system, is 12,976 fish. A total of 2,355 sockeye salmon were taken for broodstock leaving a spawning escapement of 10,621 sockeye salmon for 1996, the second highest spawning escapement since 1985 when estimates were first recorded

Figure 7. Average catches and fishing efforts computed with 1996 values for the Alaska District 111 commercial fishery and the Canadian commercial fishery in the Taku River.

The sockeye salmon count through the Kuthai Lake weir was 4,243 fish, the third highest recorded for the weir and $24 \%$ above the average count of 3,411 sockeye salmon (Appendix D.10).

The sockeye salmon count through the Nahlin weir was 2,538 fish, the third highest recorded since counts were started in 1988 and $51 \%$ above the average count of 1,681 fish.

## Chinook Salmon

Aerial surveys of the large Chinook salmon (3-ocean and larger) to the six escapement index areas annually surveyed by the ADF\&G were as follows: Nakina, 7,720; Kowatua, 1,620; Tatsamenie, 2,011; Dudidontu, 1,810; Tseta, 1,201; Nahlin, 5,415 fish (Figure 9, Appendix D.11). The total of 19,777 large Chinook salmon observed was the highest on record and over two times the 10 -year average of 9,670 fish. The interim index escapement goal for the Taku drainage is 13,200 large Chinook salmon to the six index areas.
The number of Chinook salmon carcasses counted at the Nakina River weir in 1996 was 2,679 fish. A total of 7,862 Chinook salmon was counted through the Nahlin River weir (Appendix C.10).

## Coho Salmon

Spawning escapement of coho salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tags were applied though statistical week 38 and tag recovery occurred until statistical week 40 (September 29 to October 5). Since the mark-recapture data used did not cover the full migration period, District 111 average CPUE information was fit to a normal curve to provide an estimate of the proportion of the run that was missed; the initial estimate of 44,172 was subsequently expanded by 0.889 . The above-border run was estimated to be 49,687 fish and the spawning escapement was 44,635 fish (Appendix C.7). The spawning escapement is below the 1987-1995 average of 75,358 coho salmon; however, it is above the interim escapement goal of 27,500 to 35,000 coho salmon.

## Pink Salmon

A total of 21,583 pink salmon was counted at the Canyon Island fish wheels in 1996 (Appendix D.14). There was no program in place to estimate the escapement of pink salmon to the Taku River in 1996. The pink salmon count at the fish wheels was $33 \%$ above the 1986 to 1995 average of 16,181 .

## Chum Salmon

There was no program in place to estimate the system-wide escapement of chum salmon. Low catch and CPUE information from the Canyon Island fish wheels (Appendix D.14) and inriver commercial fishery (Appendix D.5) indicated that there was a below average chum salmon run in 1996. A total of 388 chum salmon was captured in the fish wheels, $38 \%$ below the 1986-1995 average of 628 (Appendix D.14). Chum salmon were observed in four index areas that are surveyed (aerials) by the TRTFN; the count in these areas was 720 chum salmon, an above average count. The Taku River fall chum salmon run has continually declined since 1989. It is unlikely that the spawning escapement goal of 50,000 to 80,000 chum salmon was achieved.

## Steelhead Salmon

There was no program in place to estimate the system-wide steelhead salmon escapement. An escapement goal has not been set for this species.

## Sockeye Salmon Run Reconstruction

The postseason estimate of 182,428 wild Taku River sockeye salmon and 4,779 fish originating from fry plants into Tatsamenie and Trapper Lakes in the District 111 gillnet fishery were estimated from a combination of thermal mark analysis, scale pattern analysis, and brain parasite prevalence. An additional 2,977 sockeye salmon was estimated to have been harvested in the U.S. inriver personal use fishery. The estimated U.S. harvest of Taku River sockeye salmon is 190,184 fish (Table 3).
The estimate of the magnitude of the above-border sockeye salmon run in 1996, based on the joint Canada/U.S. mark-recapture program, was 134,651 fish (Table 3). Subtracting the Canadian inriver catch of 42,025 sockeye salmon in the commercial and aboriginal fisheries from the above-border run estimate results in an above-border escapement estimate of 92,626 fish.

The run size estimate, determined by summing the estimated U.S. and Canadian harvests and the escapement is 324,835 sockeye salmon, which was $52 \%$ above the 1985-1996 average run size of 213,301 fish (Appendix D.9). Based on the escapement goal range of 71,000 to 80,000 fish, the TAC was 244,835 to 253,835 sockeye salmon, of which the U.S. harvested $75 \%$ to $78 \%$ and Canada harvested $17 \%$ (Table 3). The overall exploitation rate was estimated to be $71 \%$ in 1996.

Figure 8. Sockeye salmon catches for the Alaska District 111, the Icy and Chatham Straits, the combined Canadian commercial and food fisheries in the Taku River, and Taku sockeye salmon escapements, 1979-1996.

## ALSEK RIVER

Alsek River salmon stocks contribute to the U.S. commercial gillnet fisheries located in Dry Bay, at the mouth of the Alsek River (Figure 10). Unknown quantities of Alsek origin fish are also taken in the U.S. commercial gillnet and troll fisheries in the Yakutat area. No commercial fishery exists in the Canadian portions of the Alsek River drainage, although aboriginal and recreational fisheries occur in the Tatshenshini River and some of its headwater tributaries (Figure 10).

## Harvest Regulations

Although catch sharing of Alsek salmon stocks between Canada and the U.S. has not been specified, Annex IV does call for a cooperative attempt to rebuild depressed Chinook and earlyrun sockeye salmon stocks. The Transboundary Technical Committee set interim escapement goal ranges for Alsek sockeye salmon at 33,000 to 58,000 fish and coho salmon at 5,400 to 25,000 fish. Instead of a system-wide Chinook salmon escapement goal, a revised goal, expressed in terms of the Klukshu stock only, has been established at 4,700 Chinook salmon which is currently under review. The revision made in the fall of 1991 reflected the desire to reduce the uncertainty over expansion factors that had no scientific backing.

## U.S. FISHERIES

The Dry Bay commercial set gillnet fishery harvested 771 Chinook, 15,182 sockeye, 5,514 coho, 0 pink, and 165 chum salmon (Figures 11-14, Appendix E.1). The fishery was open for 47.5 days, $9 \%$ longer than the 1986-1995 average of 43 days (Appendix E.4). The majority of fishing time (32 days) occurred late in the season (August through early October) after the sockeye salmon run had largely passed through the fishery. The total effort expended in the fishery was 438 boat-days, about 5\% less than the 1986-1995 average of 463 boat-days (Figure 11).

Preseason expectations were for an above average run of early sockeye salmon, an average run of late-run sockeye salmon and an average run of Chinook salmon. These expectations were based on parent-year escapements to the Klukshu River.
The Alsek River was opened to commercial fishing on statistical week 23, the first Monday in June (June 3). This marked the third year in a row that the Alsek was opened on the earliest date allowed by regulation. The initial opening was limited to 12 hours in order to evaluate the effectiveness of Chinook salmon conservation measures. Fishery performance indicated that the early-segment of the sockeye salmon run was average and that the Chinook salmon harvest was above expected levels. Fishing time was not extended during the initial opening. CPUE was well above average during the second week of the season, but fishing time was kept at one day due to the Chinook salmon harvest. Fishing time was increased to two days during the third week (statistical week 25; June 16 to 22) of the season and CPUE remained above average. Fishing time was increased to three days for statistical week 26, two days were allowed for statistical week 27, and three days were allowed for statistical weeks 28 through 30. CPUE was below average for statistical weeks 26 through 28. Although, during statistical weeks 26 through 28 CPUE was average or above average until effort increased during the last 24 hours of the fishing periods due to fishermen that moved from the East River to Alsek River. CPUE remained above average the remainder of the sockeye salmon season (statistical week 29 through 33; 7/14 to 8/17). Fishing periods were two days for statistical weeks 31 and 33 and four days for statistical week 32 . Only $1 \%$ of the sockeye salmon harvest occurred after statistical week 33.

Figure 9. Taku River Chinook salmon index escapement counts, 1975-1996.

Figure 10. The Alsek River and principal U.S. and Canadian fishing areas.

As a reflection of the strong area-wide coho salmon run, fishing times were maintained at four days for statistical weeks 36 through the final week of the season (statistical week 40). The coho salmon harvest of 5,514 was $23 \%$ higher than the 1986-1995 average of 4,491 coho salmon (Appendix E.4). Sitka Sound Seafoods closed their Dry Bay Plant at the end of statistical week 38. Due to the closure of the plant the fishing effort the last two weeks of the season was minimal.

Historically, a set gillnet fishery targeting on Chinook salmon was conducted during May and early June. Due to depressed runs, the directed fishery has been closed since 1962 and Chinook salmon are now harvested only incidentally during the sockeye salmon fishery in early June. In 1996, the early June periods were limited in time in order to reduce the impact on Chinook salmon. Commercial fishers were encouraged to reduce the harvest of Chinook salmon by remaining at the fishing site and releasing live fish. This voluntary program has been used with some success on the Situk River under similar circumstances. As in recent years, gillnet mesh size was restricted to a maximum of six inches through July 1. The Chinook salmon harvest of 771 fish was more than double the 1986-1995 average of 354 fish, but was slightly below the 1960-1995 average of 853 Chinook salmon (Appendix E.4). Approximately 64\% of the Chinook salmon catch ( 492 fish), was taken during the first two weeks of the season.

The Alsek River sockeye salmon harvest of 15,182 fish was about 17\% below the 1986-1995 average of 18,263 (Figure 12, Appendix E.4). The majority of the harvest ( $91 \%$, 13,755 sockeye salmon) was taken in the river, with the remainder of the catch coming from the surf area. Adjustments to the weekly fishing periods during the sockeye salmon season relied heavily on fishery performance data; the decision of whether or not to extend any given period was generally based on catch and CPUE figures gathered inseason during that particular period. Parent year escapement information and the Alsek management model projections were also factors in determining the weekly fishing periods. The management model uses multiple regression analysis of fishery catch and effort data to generate weekly projections of the U.S. Alsek River catch, the Klukshu River escapement, and total index run size (U.S. catch + Klukshu weir count). Model results tend to get more accurate as the season progresses; early season projections are of limited use for management purposes. In 1996, model projections were inaccurate. Catch was under estimated and escapement was greatly over estimated (Table 5). Various factors affect the accuracy of the model, including the relative strengths of early and late runs to Klukshu, the abundance of stocks not represented in the model (e.g., Village Creek stock), and the accuracy of manager's projections of effort levels.

Table 5. Inseason U.S. forecasts of the 1996 Alsek River sockeye salmon catch, Klukshu River weir count, and index run size (catch + Klukshu weir count).

| Statistical week | Start <br> Date | Total <br> Catch | Klukshu <br> Count | Index <br> Run |
| :--- | :--- | :--- | :--- | :--- |

## Canadian Fisheries

The center of Aboriginal fishing activity in the Alsek drainage occurs at the Champagne/Aishihik Indian village of Klukshu, on the Haines Road, about 60 km south of Haines Junction. Salmon are harvested by means of gaff and traditional fish traps as the fish migrate up the Klukshu River into Klukshu Lake. Gaff fisheries also exist on Village Creek, Goat Creek, and the Blanchard River.

As in recent years, management actions were taken to conserve Chinook and early-run sockeye salmon stocks. The fishing plan for the Aboriginal fishery for the period prior to August 15 allowed only elders to fish by means of fish-traps for 1.25 days per week. After August 15, it was planned that fishing by traps would be allowed 3.25 days per week. However, a very poor late sockeye salmon run lead to the closure of trap fishing in mid-September. This marked only the second time in the history of the fishery that a closure was implemented due to conservation concerns.
Gaffing for sockeye salmon in the Klukshu River was prohibited prior to August 15, except by elders. Conservation concerns over the late sockeye salmon run resulted in closure of the gaff fishery in the Klukshu River upstream of the weir in mid September; at this time gaffing downstream from the weir was restricted to two days per week. Gaffing for Chinook salmon was prohibited in the waters of Village Creek, Stanley Creek and the Parton River.
The Aboriginal food fishery harvested an estimated 448 Chinook, 1,204 sockeye, and 56 coho salmon. The catch of Chinook salmon was approximately $88 \%$ above the 1986-95 average of 238 fish. The sockeye salmon catch was 38\% below the 1986-95 average of 1,940. Weekly catches and annual comparisons appear in Figures 11-14 and Appendices E. 2 and E.6.

Figure 11. Average catches and fishing efforts compared with 1996 values for the Alaska Alsek River commercial fishery and the Canadian aboriginal and sport fisheries in the Alsek River.

Figure 12. Alsek sockeye salmon catches and weir counts, 1979-1996.

Figure 13. Alsek Chinook salmon catches and weir counts, 1979-1996.

Figure 14. Alsek coho salmon catches and weir counts, 1979-1996.

The majority of the sport fishing effort on this drainage occurs on the Tatshenshini River, at and just downstream of the mouth of the Klukshu River in the vicinity of the abandoned settlement of Dalton Post. Retention of sockeye salmon in the recreational fishery was prohibited prior to August 15 to protect early runs. The Chinook salmon daily catch limit was two fish, only one of which could be over 45 cm . The overall possession limits for salmon was four, of which only two could be Chinook salmon greater than 45 cm in length. Sport fishing in Dalton Post area was open from 6:00 am Saturday to 12:00 noon Tuesday each week until September 10 when the fishery was closed due to sockeye salmon conservation concerns. The closure, which remained in effect to October 19, seriously impacted the fall sport fishery for both sockeye and coho salmon. The headwater areas within the drainage, upstream of the British Columbia - Yukon border, were closed for the season to protect spawning Chinook salmon.
The recreational fishery harvested an estimated 650 Chinook, 157 sockeye and 9 coho salmon. Compared to 1986-1995 averages, the Chinook salmon catch was $85 \%$ above average, the sockeye salmon catch was $59 \%$ below average, and the coho salmon catch was $94 \%$ below average. The catch data was derived from a creel census program conducted in the Dalton Post area by the Klukshu weir personnel. Weekly estimates and annual comparisons are listed in Appendices E. 2 and E. 6.

## ESCAPEMENT

It is currently not possible to accurately assess whether the system-wide escapement goals for Alsek sockeye and coho salmon are being met because total drainage enumeration programs are not established. A large, but unknown, and presumably variable proportion of the escapement of each species is enumerated at the weir on the Klukshu River. Current escapement monitoring programs including the Klukshu weir, Village Creek electronic counter, and aerial surveys do, however, allow annual comparisons of escapement indices. The most reliable comparative escapement index for Alsek drainage salmon stocks is the Klukshu River weir count.

## Sockeye Salmon

A total of 8,320 sockeye salmon was counted through the Klukshu weir (Appendix E.7) in 1996 and consisted of below average (1986-1995) counts of: early-run, 1,502 fish (count through August 15); and late-run, 6,818 fish. The early run count was $55 \%$ below the 19865-1995 average of 3,315 fish, and the late run count was $55 \%$ below the 1986-1995 average of 15,230 sockeye salmon. The estimated Village Creek sockeye salmon escapement was 1,583 sockeye salmon, 68\% below the 1986-1995 average of 4,921 fish (Appendix E.8).

Comparative counts for other Alsek index tributaries appear in Appendix E.8. A count of 325 sockeye salmon for Basin Creek was well below the 1986-1995 average count of 1,144 fish. The maximum count for the Tanis River was 650 sockeye salmon, $47 \%$ below the 1986-1995 average of 1,223 fish.

## Chinook Salmon

The most reliable comparative escapement index for the Alsek drainage is the Klukshu weir count. The Chinook salmon weir count in 1996 of 3,599 fish was $27 \%$ above the 1986-1995 average of 2,830 fish (Figure 13, Appendix E.7). However, the 1996 count was below the interim escapement goal of 4,700 Klukshu Chinook salmon.

Aerial Chinook salmon surveys were again flown in 1996. The count of 230 Chinook salmon in the Takhanne River was below the 1986-1995 average of 242 fish by 5\%. Aerial count of 132 Chinook salmon at the Blanchard River was 63\% below the 1986-1995 averages of 355 Chinook salmon. The survey count of 12 fish at Goat Creek was $78 \%$ below the previous 10-year average of 55 fish (Appendix E.9). The aerial survey count of 788 Klukshu Chinook salmon was $22 \%$ of the weir count of 3,599 fish.

## Coho Salmon

Escapement counts for coho salmon on the U.S. side of the border were generally average. The combined systems coho salmon survey count of 1,350 fish was $22 \%$ above the 1986-1995 average of 1,103 fish (Appendix E.10).

## Run Reconstruction

Estimates of the Klukshu contribution to the sockeye salmon run to the Alsek drainage vary from $37 \%$, as estimated from an ADF\&G mark-recapture study in 1983, to $60 \%$, based on Canadian fishery managers' professional judgment. The Klukshu weir count divided by the estimated proportion of Klukshu fish that constitute the total Alsek run, minus the recreational and aboriginal fishery catches yields an escapement estimate for the Alsek River. The estimated escapement added to the U.S. commercial and subsistence catches yields an estimate of the entire Alsek run. Using the $37 \%$ to $60 \%$ contribution range, the estimated sockeye salmon escapement in the Alsek River was on the order of 12,000 (Canada) to 20,000 (U.S.) fish and the estimated Alsek sockeye salmon run was on the order of 29,000 (Canada) to 38,000 (U.S.) sockeye salmon. Based on this information, the interim sockeye salmon escapement goal of from 33,000 (U.S.) to 58,000 (Canada) for the Alsek River was not achieved.

Table 6. Catch and Klukshu index escapement data for Alsek sockeye, Chinook, and coho salmon for 1996.

| Index Type | Sockeye | Chinook | Coho |
| :--- | :--- | :--- | :--- |
| Escapement Index |  |  |  |
| Klukshu Weir Count | 8,320 | 3,599 | 3,465 |
| Klukshu Escapement | 7,891 | 3,382 | 3,465 |
|  |  |  |  |
| Harvest | 15,182 | 771 | 5,373 |
| U.S. Commercial | 39 | 14 | 18 |

| Canadian Aboriginal | 16,582 | 1,883 | 5,456 |
| Total |  |  |  |

## ENHANCEMENT ACTIVITIES

## Egg Collection

In 1996, sockeye salmon eggs were taken at Tahltan Lake on the Stikine River for the eighth year, and in the Tatsamenie Lake system on the Taku River for the seventh year. No eggs were collected at Little Trapper Lake on the Taku River in 1995 or 1996.

## Tahltan Lake: Target 6.0 million eggs

The egg collection was again contracted to Triton Environmental Consultants Ltd. The large escapement in 1996 made capture of broodstock relatively easy. An estimated 6.2 million eggs were collected from 2,128 females (based on an average historical fecundity of 2,900 eggs per female). A similar number of males were taken.

Tatsamenie Lake: Target 5.0 million eggs
Egg collection was again contracted to Mercer and Associates Ltd.-An estimated 5.0 million eggs were collected from 1,244 females (based on an estimated fecundity of 4,000 eggs per female). This is the largest number of eggs yet collected from the Tatsamenie system. Approximately the same number of males were taken. Broodstock was captured at an improved adult enumeration weir that was located on the outlet of Tatsamenie Lake. This was the third year that all of the Tatsamenie broodstock was captured at this location; in 1993 a small scale pilot project captured 44 females at this location (the majority of the broodstock in 1993, and all of the broodstock from 1990 to 1992 was captured at an adult weir on the outlet of Little Tatsamenie Lake). No significant problems were encountered during the course of broodstock collection and holding.

## Incubation and Fry Plants (1995 Brood Year)

Incubation of 1995 brood eggs took place at Snettisham Hatchery and the resultant fry were transported to the appropriate systems in June and July of 1996. The IHN virus was detected in several incubators that contained Tahltan and Tahltan/Tuya fry at Snettisham. The hatchery manager observed behavior of pre-emergent fry indicative of IHN virus and made the decision to destroy those incubators of fish; the ADF\&G pathology lab later confirmed the presence of the virus.

## Tahltan Lake

A total of 2.3 million fry from the 1995 Tahltan sockeye salmon egg take was planted back into Tahltan Lake in 1996 (Table 7). Survival from green egg to outplanted fry was $76 \%$. One incubator of fry designated for planting in Tahltan Lake was destroyed due to IHNV (330,400 fry). The otoliths of this group of fry were thermally marked with a six ring pre-hatch band. Fry outplanting took place from June 15 through June 25.

## Tuya Lake

A total of 2.5 million fry from the 1995 Tahltan sockeye salmon egg take was planted into Tuya Lake in 1996 (Table 7). Survival from green egg to outplanted fry was $64 \%$. Two incubators of fry designated for planting in Tuya Lake were destroyed due to IHNV (521,500 fry). The otoliths of this group were thermally marked with a four ring pre-hatch band. Fry outplanting took place from June 21 through July 3.

## Tatsamenie Lake

A total of 1.7 million fry from the 1995 egg take was planted into Tatsamenie Lake in 1996 (Table 7). Survival from green egg to outplanted fry was $72 \%$. IHNV was not detected in this group of fry. Otoliths of fry planted into Tatsamenie Lake were thermally marked with a five ring pre-hatch band. Outplanting took place from June 16 through June 25.

Table 7. Summary of sockeye salmon fry releases to transboundary river systems.

|  | Fry Destination |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Tahltan | Tuya | Trapper | Tatsamenie |
| 1989 | $1,042,000$ | 0 | 0 | 0 |
| 1990 | $3,600,000$ | 0 | 934,000 | 673,000 |
| 1991 | $1,400,000$ | $1,600,000$ | $1,800,000$ | $1,200,000$ |
| 1992 | $1,900,000$ | $2,000,000$ | $1,100,000$ | 909,000 |
| 1993 | 904,000 | $4,700,000$ | 916,000 | 521,000 |
| 1994 | $1,100,000$ | $2,300,000$ | 773,000 | 898,000 |
| 1995 | $2,300,000$ | $2,500,000$ | 0 | $1,700,000$ |

## OUTPLANT Evaluation Surveys

## Acoustic and trawl, Beach seine and Limnological sampling

Outplant evaluation resources were reduced in 1996. The cuts reflect a reduced budget and the loss of a full position with the retirement of one of the principal transboundary research biologists, Mr. Bruce Morley. Surveys continued to be directed by the Salmon Indexing Methods Unit of the Stock Assessment Division of Fisheries and Oceans, Canada. Limnological/beach seine surveys were conducted at Little Trapper, Tahltan, Tatsamenie, Trapper and Tuya lakes; acoustic and trawl surveys were conducted at Tahltan, Tatsamenie and Tuya lakes.
The first surveys were limnological surveys conducted by B. Mercer and Associates between July 21 and July 27. These surveys included Secchi depths; surface temperature; vertical temperature profiles; and sampling for total phosphorus, chlorophyll-a, and zooplankton. Stratified zooplankton sampling was conducted at Tuya Lake again this year. Beach seining was expanded this year to include all five lakes (Tahltan and Tuya lakes were omitted in 1995). The acoustic and trawl surveys were conducted in September by Triton Environmental Consultants Ltd.- only three lakes were surveyed this year. High fry densities, which resulted in target overlap problems in previous years, were not encountered in 1996. The total phosphorous and chlorophyll-a samples have been forwarded to the West Vancouver lab for processing. The zooplankton and fish samples collected this year are currently archived at the Pacific Biological Station awaiting assignment of budget and sample processing priorities.

Table 8. Limnetic fish population estimates and beach seine catches by broodyear in Tahltan; Tatsamenie; and Tuya Lakes. The data collected in 1996 are preliminary.

## Smolt Sampling

Trapping to obtain samples of both wild and enhanced sockeye salmon smolts was done at Tahltan, Tatsamenie, Trapper, and Tuya lakes. Sampling and enumeration at Tahltan Lake weir was conducted by DFO, Whitehorse, as part of their continuing smolt program. At Tatsamenie the work was again done under contract with Brian Mercer and Associates Ltd., and included a longer period of operation than in the past and a mark recapture study to estimate abundance of out migrants. Sampling at other lakes was done by fyke net with no attempt made to estimate run size, which is estimated from fall hydroacoustic and trawl survey data. Brian Mercer and Associates also conducted the work at Trapper and Tuya.

## Tahltan Lake

Sampling at Tahltan Lake was conducted May 11 to June 26 by DFO, Whitehorse, as part of their regular smolt enumeration program. The run was sampled daily in approximate proportion to run size. A total of 800 smolts were collected from the estimated run of $1,559,236$ smolts. A proportional subsample of 400 fish was selected for otolith thermal mark analysis. The otoliths from this subsample will be examined for marks to distinguish enhanced from wild fish.

## Tatsamenie Smolt Mark-Recapture

A new smolt program was conducted at Tatsamenie Lake from May 26 to June 28, 1996. Emigrating sockeye salmon smolts were captured in a 2 m by 2 m fyke net (with wings constructed of vexar). A subsample of the daily catch was anaesthetized using MS222, transported in a water filled container supplied with an oxygen diffuser, and released in Tatsamenie Lake about 5 km west of the lake outlet. The released smolts were marked with
color-coded paper staples applied beneath the dorsal fin. A separate color code (2 colors/tag- i.e. white-white or black-red) was used each day for a 10 -day period and the same color code sequence was then repeated for the next 10-day period. Numbered fingerling tags were tested early in the program, but the use of this tag type was discontinued due to the excessive handling required and potential injury to the smolts. This program was fashioned after a smolt mark recapture program that has been conducted on the Babine River since the 1960's. The staple tags were bent in a jig and applied by hand; taggers used bandages on the thumb and near thumb digit to facilitate tag application.
A total of 29,787 smolts were caught, 9,712 tags were applied and 614 tags recovered over the course of the study. Population estimates were calculated on a daily basis; the cumulative estimate is 469,114 smolts, although the estimate does not cover the full migration period, and was not adjusted for net efficiency.
Two control groups of 20 smolts were held in net pens in the river for 10 days. There was no tag loss observed, $5 \%$ of one control group died on the 8th day. Virtually all of the marked fish released in the lake emigrated prior to 8 days, however, if fish died there could be increased susceptibility to predation.

Approximately 400 smolts were collected throughout the run, sampled for length, weight, and scales and preserved for thermal mark analysis. The otoliths from this subsample will be examined for marks to distinguish enhanced from wild fish. The results of this analysis when completed can be weighted on a daily basis to determine the total number of wild and enhanced smolts emigrating from Tatsamenie Lake.

## Tuya Lake

All Tuya smolts collected in 1996 were considered to be age 1+ fish (the samples have not been aged yet); they were 12-15 grams in weight. Analysis of thermal marked otoliths and aging of scales is not complete at this time.

## Trapper Lake

Fyke nets were fished mid-stream under favorable water conditions from May 22 to June 20; only 100 smolts were captured. Size information suggests that the sample involved 3 age groups. All age $1+$ were $6-7$ grams. These fish were heavier than previous averages, and may have been from the group with a unique mark that was held and fed in a net pen in 1995. Analysis of thermal marked otoliths and aging of scales is not complete at this time.

## Final Results - 1995 Smolts

Processing of 1995 smolts was completed over the winter at the otolith lab in Nanaimo. Results are presented in Table 9.

Table 9. Enhanced and wild contribution, and average length and weight for transboundary sockeye smolts emigrants sampled in 1995, by site.

| Site | Age Composition (\%) |  |  | Length |  | Weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Origin | 1.0 | 2.0 | 1.0 | 2.0 | 1.0 | 2.0 |
| Tahltan | Wild | 90.4 | 2.8 | 83.4 | 116.7 | 4.7 | 13.5 |
|  | Enhanced | 5.4 | 1.3 | 81.7 | 113.0 | 4.4 | 12.0 |
| Tuya | Wild | n/a | n/a | - | - | - | - |
|  | Enhanced | 97.1 | 2.9 | 95.6 | 137.0 | 9.6 | 27.4 |
| Tatsamenie | Wild | 84.8 | 12.7 | 81.9 | 119.3 | 5.1 | 16.1 |
|  | Enhanced | 2.0 | 0.5 | 79.5 | 117.0 | 4.5 | 15.2 |
| Trapper ${ }^{\text {a }}$ | Wild | n/a | n/a | - | - | - | - |
|  | Enhanced | 6.1 | 89.1 | 84.7 | 111.0 | 6.0 | 13.7 |
| L. Trapper | Wild | 64.1 | 33.1 | 66.5 | 80.9 | 2.8 | 4.8 |
|  | Enhanced | 0.4 | 2.4 | 69.0 | 110.7 | 3.2 | 13.4 |

${ }^{a}$ Additional smolts at Trapper were 4.2\% age 3.0 and $0.6 \%$ (1 fish) age 4.0.

## Central Incubation Facility

The Snettisham Hatchery Central Incubation Facility operated very well during the last year. The otolith marks applied were of good quality based on the voucher samples analyzed by the ADF\&G otolith lab. All newly installed systems are functioning well and staffing of the hatchery has undergone some positive changes.

The State of Alaska transferred the operation of Snettisham from ADF\&G to DIPAC hatchery, a private aquaculture organization with two other operational hatcheries in Juneau. A cooperative agreement between ADF\&G and DIPAC provides for Snettisham to continue to serve the needs of the joint transboundary river enhancement projects. The transfer took effect on July 1, 1996; the new managers are doing an excellent job of hatchery operation.

## Otolith Analysis

## U.S. Otolith Lab

Activities of the Alaska Department of Fish and Game's Otolith Processing Laboratory included: 1) sampling otoliths from Districts 106, 108, and 111 commercial fisheries; 2) processing a subsample of otoliths to provide weekly in-season estimates to fisheries managers on the contribution of enhanced stocks from the 1990 through 1992 broodyears for use in management decisions; 2) post-season processing a portion of the remaining otoliths to determine overall contribution of enhanced fish in the commercial fisheries; and 3) conducting quality control assessments on the readability of the thermal mark through the use of independent second readings.
During this reporting period the collection of sockeye salmon otoliths from commercial gillnet fisheries targeting on Stikine River and Taku River stocks was completed along with the final processing of otoliths to estimate stock contribution.

The sampling program, conducted primarily out of Petersburg, went fairly smoothly. However every year presents it's own challenges. This year problems were associated with the huge run of chum salmon that returned to southeast Alaska. These chum salmon created difficulties for the fisherman in trying to target on sockeye salmon and it also made it difficult for the processors to sort the sockeye salmon from the chum salmon and to schedule processing time to handle the high volume of fish. As a result it was sometimes difficult for samplers to track the progress of the fishery during the season such that they could schedule their time to obtain samples. Overall however these difficulties were worked through and the samples received by the ADF\&G Tag and Otolith lab are believed to be unbiased and representative of the commercial catch.
The fisheries sampled in 1996 include Frederick Sound driftnet (District. 108-50,60), Wrangle Area driftnet (District. $108-20 / 30 / 40$ ), Sumner Strait driftnet (District. 106-41), Upper Clarence Strait driftnet (District. 106 -30), and TakulSnettisham driftnet (District. 111-31,32). On a weekly basis, 288 to 300 otolith pairs were randomly collected from both the Sumner Strait and Upper Clarence Strait fisheries, and 200 otoliths were collected from both the Wrangle area and Frederick Sound driftnet fisheries. Unlike previous years, matched scale and otolith samples were obtained from the first 100 otoliths per week in the Sumner Strait fisheries to help identify, through scale analysis, stocks whose scale patterns could potentially be confused with the Tuya fish. In the Taku/Snettisham driftnet fisheries, 400 matched samples of scales, brain parasites and otoliths were collected per week. These matched samples are necessary to provide stock separation analysis to identify different wild stocks.

For each fishery opening 100 of the otoliths were processed within 48 to 72 hours to provide the fisheries managers an estimate of stock composition. Portions of the remaining otoliths were later processed to increase precision around the initial estimates.
Staff were able to keep up with the volume of samples received inseason and provide to ADF\&G managers estimates on hatchery contribution in five separate fishery openings per week. These estimates provided information on run timing and abundance of enhanced fish and were available for use by managers in making decisions about the duration and timing of future commercial openings.
By the end of the season Department of Fish and Game port samplers collected 10,369 otolith pairs from 57 fishery openings over a 10 -week period. Of these, 7,240 otoliths were extracted from 39 separate fisheries openings in districts 106 and 108 targeting the Stikine River stocks and 3,129 otoliths were taken from 18 openings in the District 111 fisheries targeting the Taku River stocks. Laboratory personnel have processed $67 \%$ of the Stikine samples and nearly $100 \%$ of the Taku samples. The number of Stikine otoliths processed are determined by an optimizing algorithm that minimizes the overall uncertainty on the proportion of enhanced fish in the commercial fisheries, while all the Taku samples are processed because of the need for identifying the enhanced fish prior to running scale stock separation analysis.
Table 10 presents a summary of all the otoliths processed from statistical week 24 (June 10) through statistical week 34 (Aug. 18) grouped by fishing district. The table includes estimates of percent contribution of otolith marked fish captured in each district. The total Taku River figures include all the District 111-31 and -32 fisheries and include a commercial opening that took place in District 111-35 to target on domestic stocks returning to the Port Snettisham hatchery.

Table 10. Sockeye otolith collection data.

| Fisheries | Subdistricts | Otoliths <br> Sampled | Otoliths <br> Processed | Percent <br> Marked |
| :--- | ---: | ---: | :---: | :---: |
| Frederick Sound | $108-50,60$ | 1,411 | 1,120 | $10.8 \%$ |
| Wrangle area | $108-20,30,40$ | 1,107 | 911 | $17.5 \%$ |
| Sumner Strait | $106-41,42$ | 2,547 | 1,901 | $6.2 \%$ |
| Upper Clarence Strait | $106-30$ | 2,171 | 935 | $0.4 \%$ |
| Taku/Snettisham | $111-31,32,35$ | 3,129 | 3,122 | $3.4 \%$ |

Examination of the second readings for quality control suggests that there was overall good agreement on what is marked and unmarked fish. As a result it is likely that the numbers presented in Table 1 will be fairly close to the final figures. A goal for quality control readings is to ensure that uncertainty due to reading errors is smaller than the uncertainty that is due to sample size alone. Because reading thermal marks is ultimately a subjective determination and no secondary tag has been applied to these fish, we can only estimate the accuracy of the readings through blind replicate readings of the thermal marks. The experience to date is that even with clear thermal marks there will still be disagreements between experienced readers and the effective accuracy in readings will be something less than $100 \%$. We have also found that there tends to be greater disagreement in distinguishing between marked groups as opposed to distinguishing between marked and unmarked fish.

At this point we suspect that the disagreement within marked groups might be a result of how often the pattern is encountered by the readers. Human visual theory suggests that the recognition of complex patterns is directly related to exposure to the patterns. We will continue to look for ways to improve the detection on seldom encountered patterns during the season by trying various methods that aid in the development of a mental 'search image'. One reason for improving this capability is that uncommon patterns are frequently those from age- 4 sockeye salmon. The proportion of age 4 fish encountered during the year is useful in estimating the number of 5 -year-olds (the dominant age) that will return the following year. In the past we have presumed the detection of 4-year-old marked fish was $100 \%$ accurate and that information was used to monitor the effectiveness of the enhancement program. This presumption of accuracy will be reevaluated through between reader comparisons as well as between laboratory comparisons through the exchange of samples with the Canadian otolith laboratory.

## Canadian Otolith Lab

DFO began developing capabilities to examine for the presence of otolith marks in 1994. A term technician was hired in September of 1994 to work at the Pacific Biological Station, Nanaimo. He has visited otolith labs in both Juneau and Olympia (Washington Dept. of Fisheries) to observe techniques and develop standardized terminology. The lab is now processing otoliths from a number or southern British Columbia hatcheries (mainly Chinook salmon) and will be processing all 1996 transboundary juvenile and smolt otolith samples and most, if not all, of the Canadian transboundary adult samples. Although the lab is not currently funded as, or intended to be, a support service, this is the eventual goal.

## APPENDIX A

Appendix A. 1. Weekly salmon catch and effort in the Alaskan Subdistrict 106-41\&42 (Sumner Strait) commercial drift gillnet fishery, 1996.

Appendix A. 12. Weekly sockeye salmon stock proportions and catch by stock in the Canadian commercial fishery in the lower Stikine River, 1996. Sex specific age compositions were calculated and the stock composition of the females sampled for egg diameters was expanded to the catch by age. Thermal mark information based on recovery ratios of Tahltan and Tuya fish in 108.

Note: The proportions used for the final estimate include interpolations for week 25.

Appendix A. 17. Weekly catch, CPUE, and migratory timing of Tahltan and Mainstem sockeye salmon stocks in the Stikine River test fishery, 1996. Sex specific age compositions were calculated and the smoothed stock compositions of the females sampled for egg diameters were expanded to the catch by age.

${ }^{a}$ Tahltan includes wild and thermally marked fish.

Appendix B. 5. Salmon catch and effort in the Alaskan District 106 commercial drift gillnet fisheries, 1964-1996. Catches do not include Blind Slough terminal area harvests. Effort may be less than the sum of effort from106-41/42 and 106-30 since some boats fished in more than one subdistrict.

Appendix C. 7. Mark-recapture estimate of above border run of sockeye and coho salmon in the Taku River, 1996. The early season sockeye salmon expansion is based on the proportion of fish wheel sockeye salmon catch that occurs before the fishery opens and the late season expansion for coho salmon is based on the proportion of the CPUE of above border coho salmon stocks in the District 111-32 fishery that occurs after the tagging is stopped.

${ }^{\text {a }}$ Mark-recapture estimates.
${ }^{\mathrm{b}}$ Weir count plus spawning ground survey.
${ }^{\mathrm{c}}$ Weir counts are incomplete.
${ }^{\text {d }}$ Counts may be low due to uncounted fish passage past weir.
${ }^{e}$ In 1995 the weir was moved upstream to Tatsamenie Lake, the count of 8,000 is an expansion (based on past experience) of the 5,780 fish counted .
${ }^{\mathrm{f}}$ The estimated return of 10,381 through the Tatsamenie Lake weir is thought to represent approximately $80 \%$ of the sockeye run past the old weir located at
L.Tatsamenie. This results in a potential run of 12,976 sockeye salmon.

Appendix D. 12. Taku River (above border) coho salmon run size, 1987-1996.

| Year | Canadian Catch |  |  | Above Border |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Commercial | Food | Test | Escapement | Run |
| 1987 | 5,599 | 113 | 807 | 55,457 | 61,976 ${ }^{\text {a }}$ |
| 1988 | 3,123 | 98 | 422 | 39,450 | $43,093{ }^{\text {b }}$ |
| 1989 | 2,876 | 146 | 1,011 | 56,808 | 60,841 ${ }^{\text {c }}$ |
| 1990 | 3,207 | 6 | 472 | 72,196 | 75,881 ${ }^{\text {d }}$ |
| 1991 | 3,415 | 20 | 2,004 | 127,484 | 132,923 |
| 1992 | 4,077 | 187 | 1,277 | 84,853 | 90,394 ${ }^{\text {e }}$ |
| 1993 | 3,033 | 8 | 1,593 | 109,457 | 114,091 ${ }^{\text {f }}$ |
| 1994 | 14,531 | 162 | 0 | 96,343 | $111,036{ }^{\text {g }}$ |
| 1995 | 13,629 | 109 | 0 | 55,710 | 69,448 ${ }^{\text {h }}$ |
| 87-95 average | 5,943 | 94 | 843 | 77,529 | 84,409 |
| 1996 | 5,028 | 24 | 0 | 44,635 | 49,687 ${ }^{\text {i }}$ |

${ }^{\text {a }}$ Mark-recapture estimate through 9/20 was 43,570. Run through 10/05 estimated using inriver test fish CPUE.
${ }^{\mathrm{b}}$ Mark-recapture estimate through 9/18.
${ }^{\mathrm{c}}$ Mark-recapture estimate through 10/01.
${ }^{d}$ A second method of estimating the above border run by expanding test fishery CPUE yielded an estimate of 85,053 coho salmon.
${ }^{e}$ Mark-recapture estimate of inriver run size through $9 / 05$ of 50,249 was expanded by dividing by proportion of District 111 CPUE of wild coho ( 0.559 ).
${ }^{\mathrm{f}}$ Inriver estimate through week 37 expanded by dividing by proportion of District 111 CPUE of wild coho $(0.54409)$ through week 37.
${ }^{\mathrm{g}}$ Inriver estimate through week 39 expanded by dividing by proportion of District 111 CPUE of wild coho ( 0.8884 ) through week 39.
${ }^{\mathrm{h}}$ Inriver estimate through week 39 expanded by dividing by proportion of District 111 CPUE of wild coho $(0.8887)$ through week 39.
${ }^{\mathrm{i}}$ Inriver estimate through week 39 expanded by dividing by proportion of District 111 CPUE of wild coho (0.889) through week 39.

Appendix D. 13. Escapement counts of Taku River coho salmon, 1984-1996. Counts are for age-. 1 fish and do not include jacks. Because of variability between methods, visibility, observers, and timing, these counts are not an index of run strength.

${ }^{\text {a }}$ Counts include jack Chinook salmon.
${ }^{\mathrm{b}}$ Includes sockeye counts up to and including August 15.
${ }^{\mathrm{c}}$ Weir was removed prior to the end of the coho run.
${ }^{\mathrm{d}}$ The Chinook and sockeye escapements into Klukshu Lake are calculated from the weir count minus fish harvested above the weir site minus brood stock taken. The remainder of the food fishery harvest occurred below the weir, at Village Creek, and Blanchard and Takhanne Rivers.

Appendix E. 8. Alsek River sockeye salmon counts from U.S. and Canadian aerial surveys and from the electronic counter at Village Creek, 1985-1996.

${ }^{\text {a }}$ Surveys not made every year at each tributary.
${ }^{\mathrm{b}}$ Includes several streams from Lo-Fog to Goat Creek.
${ }^{\text {c }}$ Incomplete count due to machine malfunction.
${ }^{d}$ Estimated count based on absolute electronic records $(5,313)$ and the total number of non-operational days.
${ }^{e}$ Estimated count based on absolute electronic records $(3,981)$ and the total number of non-operational days.
${ }^{\mathrm{f}}$ Counts were estimated during the non-operational days by averaging the counts recorded three days before and before and three days after the malfunction.
${ }^{8}$ Estimated count based on absolute electronic records $(2,101)$ and the total number of non-operational days.
${ }^{\mathrm{h}}$ Estimated count based on absolute electronic records $(3,921)$ and the total number of non-operational days.

| $86-95$ average | 1,103 |
| 1996 | 1,350 |
| ${ }^{\text {a }}$ Few systems surveyed. |  |

${ }^{a}$ Few systems surveyed.

[^0]:    ${ }^{a}$ Alaska hatchery pink salmon contributions are not estimated due to a lack of cwt data.

[^1]:    ${ }^{\text {a }}$ Tahltan includes wild and thermally marked fish.
    ${ }^{\mathrm{b}}$ There was no data available to determine the ratio of Tahltan to Mainstem Stikine stocks; a 1:1 ratio was assumed.

[^2]:    ${ }^{\mathrm{a}}$ Chum salmon are not included because of the difficulty of making an accurate estimate, the majority of the summer chum catch was of hatchery origin.

[^3]:    ${ }^{\text {a }}$ Proportion estimated from the ratio in the US District 111 catch.

[^4]:    ${ }^{a}$ The Trapper and Mainstem groups were combined in the 1989 analysis.
    ${ }^{\mathrm{b}}$ Averages for individual stocks do not include 1989.
