## APPENDICES

Appendix A. 1. Weekly salmon catch in the Alaskan District 106 commercial drift gillnet fisheries, 2007 ..... 67
Appendix A. 2. Weekly stock proportions of sockeye salmon harvested in the Alaskan District 106 commercial drift gillnet fisheries, 2007 ..... 68
Appendix A. 3. Weekly salmon catch and effort in the Alaskan Subdistrict 106-41\&42 (Sumner Strait) commercial drift gillnet fishery, 2007 ..... 69
Appendix A. 4. Weekly stock proportions and catches of sockeye salmon harvested in the Alaskan Subdistrict 106-41\&42 (Sumner Strait) commercial drift gillnet fishery, 2007 ..... 70
Appendix A. 5. Weekly salmon catch and effort in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 2007. ..... 71
Appendix A. 6. Weekly stock proportions and catches of sockeye salmon harvested in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 2007. ..... 72
Appendix A. 7. Weekly salmon catch and effort in the Alaskan District 108 commercial drift gillnet fishery, 2007 ..... 73
Appendix A. 8. Weekly stock proportions and stock-specific catch of sockeye salmon in the Alaskan District 108 commercial drift gillnet fishery, 2007 ..... 75
Appendix A. 9. Weekly salmon catch and effort and sockeye salmon stock composition in the Alaskan District 108 test fishery, 2007. There was no marine test fishery in 2007 ..... 76
Appendix A. 10. Inseason estimates of gillnet, troll, recreational, and subsistence catch of Stikine River bound Chinook salmon in District 108, 2007. ..... 76
Appendix A. 11. U.S. subsistence fishery harvest in the Stikine River, 2007 ..... 76
Appendix A. 12. Weekly salmon and steelhead trout catch and effort in the Canadian commercial fishery in the lower Stikine River, 2007 ..... 77
Appendix A. 13. Weekly sockeye salmon stock proportions and catch by stock in the Canadian commercial fishery in the lower Stikine River, 2007 ..... 78
Appendix A. 14. Weekly salmon and steelhead trout catch and effort in the Canadian commercial fishery in the upper Stikine River, 2007 ..... 79
Appendix A. 15. Weekly salmon and steelhead trout catch and effort in the Canadian Aboriginal fishery located at Telegraph Creek, on the Stikine River, 2007. ..... 79
Appendix A. 16. Catch by stock and week for sockeye salmon harvested in the Canadian upper river commercial and Aboriginal fisheries in the Stikine River, 2007. ..... 80
Appendix A. 17. Weekly salmon and steelhead trout catch and effort in the Canadian test fishery in the Stikine River, 2007 ..... 81
Appendix A. 18. Weekly catch, CPUE, and migratory timing of Tahltan, Tuya, and mainstem sockeye salmon stocks in the Stikine test fishery, 2007 ..... 82
Appendix A. 19. Daily counts of adult sockeye salmon passing through Tahltan Lake weir, 2007. ..... 83
Appendix A. 20. Daily counts of sockeye salmon smolt migrating through Tahltan Lake smolt weir, 2007 ..... 84
Appendix A. 21. Daily counts of adult Chinook salmon passing through Little Tahltan weir, 2007 ..... 85
Appendix B. 1. Salmon catch and effort in the Alaskan District 106 commercial drift gillnet fisheries, 1960-2007 ..... 86
Appendix B. 2. Stock proportions and catches of sockeye salmon in the Alaskan District 106 commercial drift gillnet fisheries, 1982-2007. ..... 88
Appendix B. 3. Salmon catch and effort in the Alaskan Subdistrict 106-41/42 (Sumner Strait) commercial drift gillnet fishery, 1960-2007 ..... 89
Appendix B. 4. Stock proportions and catches of sockeye salmon in the Alaskan Subdistrict 106-41/42 (Sumner Strait) commercial drift gillnet fishery, 1985-2007.90
Appendix B. 5. Salmon catch and effort in the Alaskan Subdistrict 106-30 (Clarence Strait) commercial drift gillnet fishery, 1960-2007 ..... 91
Appendix B. 6. Stock proportions and catches of sockeye salmon in the Alaskan Subdistrict 106- 30 (Clarence Strait) commercial drift gillnet fishery, 1985-2007 ..... 92

## EXECUTIVE SUMMARY

Postseason estimates of harvests and escapements of Pacific salmon returning to the transboundary Stikine, Taku, and Alsek Rivers for 2007 are presented and compared with historical patterns. Average, unless stated differently, refers to the 1997-2006 average. Relevant information pertaining to the management of appropriate U.S. and Canadian fisheries is presented and the use of inseason management models is discussed. Final results from transboundary river sockeye salmon Oncorhynchus nerka enhancement projects are also reviewed.

## Stikine River

The 2007 Stikine River sockeye salmon run was estimated to be 197,000 fish, Approximately 148,000 fish were harvested in various fisheries including test fisheries and an estimated 49,000 fish escaped to spawn, including 7,000 fish that migrated to the Tuya River block that were not harvested. The run and harvest were above the averages. The Tahltan Lake sockeye escapement of 21,000 fish was within the goal range ( 18,000 to 30,000 fish). The estimated U.S. commercial catch of Stikine River sockeye salmon in Districts 106 and 108, including the Stikine River subsistence fishery, was 87,000 fish. The Canadian inriver commercial and aboriginal fishery catches were 58,000 and 2,000 fish, respectively. The inriver test fishery harvested 1,000 sockeye salmon and there was no marine test fishery in 2007. Weekly inseason run projections from the Stikine Management Model (SMM) ranged from 204,000 to 278,000 sockeye salmon; the final inseason model prediction was 225,000 fish, with a total allowable catch (TAC) of 163,000 fish. Based on the postseason run size estimates and TAC calculations of 62,000 Stikine River fish for each country, Canada harvested $90 \%$ and the U.S. harvested $129 \%$ of their respective TACs. Broodstock collection and otolith sampling removed 2,800 and 200 sockeye salmon, respectively, from the escapement to Tahltan Lake leaving a spawning escapement of 18,000 fish. The estimated spawning escapement of 21,000 mainstem Stikine River sockeye salmon was within the goal range of 20,000 to 40,000 fish for this stock group.

The 2007 Stikine River Chinook salmon (non-jack salmon) run was estimated at 39,000 fish, of which approximately 24,000 fish were harvested in various fisheries. An estimated 15,000 Stikine River fish escaped to spawn, which was below the escapement goal of 21,000 large Chinook salmon. The run and harvest were below the averages. The Little Tahltan River Chinook salmon escapement of 560 fish was below the 2005 escapement goal of 4,000 fish and was the lowest on record. The estimated U.S. commercial catch of Stikine River Chinook salmon in Districts 106 and 108 gillnet, troll, subsistence, and sport fisheries was 15,000 fish. The Canadian commercial, aboriginal, and sport fishery catches were $10,000,400$, and 0 fish, respectively. There were no inriver or marine test fisheries for Chinook salmon in 2007. Managers used both the m-r and model estimates to generate inseason estimates after week 22 . The inseason run projections were persistent throughout the course of the fishery in predicting a total run size larger than the preseason forecast of 37,000 fish. Weekly inseason run projections from the model ranged from 42,000 to 50,000 Chinook salmon. The final inseason model
prediction was 39,000 fish with a TAC of 21,000 fish. The U.S. harvested approximately $132 \%$ of their TAC while Canada harvested $99 \%$ of their TAC.

The 2007 run size of Stikine River coho salmon cannot be quantified. The U.S. marine harvest of Stikine River coho salmon is also unknown since there is no stock identification program for this species. Mixed stock coho salmon harvest in Districts 106 and 108 were 81,000 and 20,000 fish, respectively. Alaskan hatchery fish comprised approximately $42 \%$ of the coho salmon harvest from the two districts. The Canadian inriver coho salmon catch of 50 fish was below average. The aerial survey count of 1,500 fish from six index sites combined was below average.

## Taku River

The 2007 Taku River sockeye salmon run was estimated to be 170,000 fish, including an catch of 82,000 fish and an above-border spawning escapement of 88,000 sockeye salmon. The run size was below average but the escapement was above the goal range of 71,000 to 80,000 fish. The U.S. harvested an estimated 65,000 Taku River sockeye salmon in the District 111 commercial fishery and 600 sockeye salmon in the inriver personal use fishery; both were below average. Canadian inriver commercial and aboriginal fishery harvests included 17,000 and 200 sockeye salmon, respectively; both below average. The U.S. harvested an estimated $69 \%$ of the total TAC and Canada harvested an estimated $18 \%$ of the TAC.

The harvest of large Chinook salmon in the Canadian commercial fishery in the Taku River was 900 fish, which is below average. The harvest in the stock assessment fishery (weeks 18-24) was 1,400 fish. Preseason and then inseason estimates of Chinook salmon abundance did not allow for a directed Chinook salmon fishery this season. The Canadian aboriginal fishery in the Taku River harvested 200 large Chinook salmon which is average. District 111 mixed stock gillnet fishery harvest of 1,200 large Chinook salmon, and was below average. Approximately $19 \%$ of the harvest was estimated to be of Alaska hatchery origin. The above border spawning escapement estimated from the markrecapture program is 18,000 fish.

The estimated above border run of Taku River coho salmon in 2007 is 82,000 fish, which is below average. The Canadian inriver commercial and test fishery harvest included 8,000 coho salmon, which is above average. After upriver Canadian harvest and test fishery catches are subtracted from the inriver run, the above-border-spawning escapement is estimated at 74,000 coho salmon, which exceeds the minimum escapement goal of 38,000 fish. The U.S. harvest of 51,000 coho salmon in the District 111 mixed stock fishery was also below average. Alaskan hatcheries contributed an estimated $2 \%$ of the District 111 harvest.

The harvest of 100,000 pink salmon in District 111 was below the odd-year average. No pink salmon were reported retained in the Canadian commercial inriver fishery in 2007. Although spawning escapement is not know the Canyon Island fish wheel catch of 12,000 fish was below average.

The catch of chum salmon in the District 111 fishery was 582,000 summer run fish and 8,000 fall run fish; both were above average. There was non-retention of chum salmon in the Canadian inriver fishery and there was no reported catch in 2007. Although spawning escapement is not known the Canyon Island fish wheel catch of 500 chum salmon was above average.

## Alsek River

The Alsek River sockeye salmon harvest of 20,000 fish in the U.S. commercial fishery was above average. The Canadian inriver sockeye salmon harvest was not available. The Klukshu River weir count of 9,000 sockeye salmon was below average but within the goal range of 7,500 to 15,000 fish. The count of 3,000 early run sockeye salmon (count through August 15) was average. The late run count of 6,000 fish was below average.

The Chinook salmon run to the Alsek River appeared to be below average. The U.S. Dry Bay catch of 400 large Chinook salmon was below average. The Canadian recreational fishery catch of 40 fish is below average and the aboriginal fishery catch was not available. The 700 Chinook salmon counted through the Klukshu River weir was also below average and below the goal range of 1,100 to 2,300 Chinook salmon.

Current stock assessment programs prevent an accurate comparison of the Alsek River coho salmon run with historical runs. The U.S. Dry Bay catch of 100 coho salmon was below average, to date, no catches have been recorded for the Canadian inriver aboriginal fishery. The operation of the Klukshu weir does not provide a complete enumeration of coho salmon into this system since it is removed before the run is over; however, it does provide an annual index. The count of 300 coho salmon is below average.

## Enhancement

Eggs and milt were collected from the 2007 sockeye salmon escapements at Tahltan, Tatsamenie and Little Trapper lakes. A total of 4 million eggs were collected at Tahltan Lake, 3.7 million at Tatsamenie Lake and 0.95 million at Trapper Lake. ( 0.1 million of the Trapper eggs were planted in Tunjony Creek).

Outplants of 2006 brood-year sockeye salmon fry in May and June 2007 included, 1.5 million fry into Tahltan Lake, 1.5 million fry into Tuya Lake, 2.1 million fry into Tatsamenie Lake and 0.9 million fry into Trapper Lake. Green-egg to planted-fry survivals were $70 \%, 83 \%, 58 \%$ and $81 \%$ for the Tahltan, Tuya, Tatsamenie and Trapper outplants, respectively. Survival to emergence was about average.

The egg incubation and thermal-marking program was continued at Snettisham Hatchery in 2007. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADFG and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Adult sockeye salmon otoliths were processed inseason by the ADFG otolith lab to estimate the weekly contribution of fish from US/Canada TBR fry planting programs to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Final contribution estimates of planted fish to Alaskan harvest were 59,000 planted Stikine River fish to District 106 and 108, and 3,700 planted Taku River fish to District 111. Final estimates of contributions to Canadian fisheries included 30,000 planted fish to Stikine River fisheries and 1,600 planted fish to the Taku River fisheries.

## INTRODUCTION

This report presents final estimates of the 2007 catch and escapement data for Pacific salmon runs to the transboundary Stikine, Taku, and Alsek Rivers and discusses management actions taken during the season. Catch and effort data are presented by management week (U.S. statistical week), hereafter referred to as week, for each river for both U.S. and Canadian fisheries. Spawning escapement data for most species are reported from weir counts or other escapement monitoring techniques. Joint enhancement activities on the Stikine and Taku Rivers are also summarized.

The Transboundary Technical Committee (TTC) met prior to the season to update joint management, stock assessment and enhancement plans and determine preseason forecasts and outlooks for run strengths and initial total allowable catch TAC estimates for the various species and rivers. The results of this meeting are summarized in: Pacific Salmon Commission Transboundary Technical Committee, Salmon Management and Enhancement Plans for the Stikine, Taku and Alsek Rivers, 2007. TCTR (07)-3.

Run reconstruction analyses are conducted on the sockeye salmon Oncorhynchus nerka and Chinook salmon $O$. tshawytscha runs to the three rivers and on coho salmon $O$. kisutch runs to the Taku for the purpose of evaluating the stocks and the fisheries managed for these stocks. No estimates of marine catch are made for Alaskan fisheries outside of District 106 and 108 for Stikine River stocks, District 111 for Taku River stocks and Sub-district 182-30 \& 31 for Alsek River stocks.

## STIKINE RIVER

Stikine River salmon are harvested by U.S. commercial gillnet fisheries in Alaskan Districts 106 and 108, by Canadian commercial gillnet fisheries located in the lower and upper Stikine River, and by a Canadian aboriginal fishery in the upper portion of the river (Figure 1). In addition, Canadian terminal area fisheries are operated in the lower Tuya River and/or at Tahltan Lake when escapements are estimated to include excess salmon to spawning requirements (ESSR). A recreational fishery also exists in the Canadian sections of the Stikine River drainage. In 1995, a United States personal use fishery was established in the lower Stikine River; no catches were reported in this fishery in 1995 through 2000, approximately 30 sockeye salmon were harvested in 2001, and the personal use fishery on the Stikine River was not open in 2002 and 2003. A subsistence fishery was opened in 2004. Additional catches of unknown quantity are taken in U.S. troll and seine fisheries and in sport fisheries near Wrangell and Petersburg. In 1996, the spring experimental troll area in the District 110 portion of Frederick Sound was expanded to target hatchery Chinook salmon; four previous areas were combined into one large area that also included previously unopened waters. This area was the same in 2003. In 1993 the spring experimental troll fishery near Wrangell was expanded to include two new areas in portions of District 106 and 108 to target hatchery Chinook salmon. In 1998 an additional area was included in a portion of District 108.

Figure 1. The Stikine River and principal U.S. and Canadian fishing areas.

## Harvest Regulations and the Joint Management Model

Negotiations between Canada and the United States to replace expired portions of Annex IV, Chapter 1 of the Pacific Salmon Treaty resulted in the following arrangements for Stikine River salmon which are expected to be in place through 2008. Highlights of the most recent round of the PSC negotiations held in Portland, Oregon in February 2005 included: an agreement for new directed fisheries for Stikine River Chinook salmon stocks; an agreement on a US subsistence fishery on Chinook and coho salmon stocks within the US section of the Stikine River; and, an agreement to ensure the U.S. pass 1,000 additional coho salmon to the Canadian fishery. Details of the February 2005 agreement including harvest sharing provisions have been incorporated into the Transboundary Annex (Annex IV) of the Pacific Salmon Treaty and can be found at: http://www.psc.org/pubs/treaty.pdf.

As in most previous years, the Transboundary Technical Committee (TTC) met prior to the season to update joint management and enhancement plans, develop run forecasts and determine new parameters for input into the inseason Chinook and sockeye salmon run projection models. The nascent Chinook salmon model, the Stikine Chinook Management Model (SCMM), served as the principal management tool governing weekly fishing regimes for the new directed Stikine River Chinook salmon. The SCMM was complemented inseason with a concurrent mark-capture study. The sockeye salmon model is referred to as the Stikine Management Model (SMM).

## Chinook Salmon

The SCMM model is based on the linear regression (correlation) between weekly cumulative catch per unit effort (CPUE) of large Chinook salmon at the tagging site and total run size based on mark-recapture studies conducted in 1996-2006. Most of the CPUE and run size data sets are significantly correlated. Mark-recapture estimates based on the cumulative ratio of tagged-to-untagged fish observed in the inriver commercial fishery were also generated commencing in week 24. In order to honor Annex IV, Chapter1, Paragraph 3(a)(3)(vii), which obliges the Parties to apportion their overall TAC by historical weekly run timing, weekly fishery openings were announced based on weekly guideline harvests. The Canadian guideline harvests were derived from historical run timing data from the 2005 and 2006 inriver commercial fisheries and the 2000-03 inriver test fisheries. The U.S. guidelines were derived from historical run timing in District 108 (1969-73, 2005-2006) and historical CPUE from the Kakwan Point tagging site, delayed one week (1996-04) and the 2001-2003 average CPUE from the Canadian Chinook salmon test fishery delayed one week.

The preseason Chinook salmon forecast was used during weeks 19-20. After week 21, inseason forecasts of total run size and TAC, were used to assist in determining weekly fishing plans (Table 1). After week 24, mark-capture estimates were generated to complement the SCMM estimate; the average run size generated from the mark-recapture estimates and the SCMM were used to project inseason run size in some weeks. The weekly inputs to the model included: the catch and effort data from Kakwan Point, the District 108 sport, troll, and gillnet catch. The Canadian sport and gillnet catches were
also added to the model. Weekly guideline quotas were established in District 108 and Canada based on the historical run timing curves mentioned above.

Table 1. Stikine River large Chinook salmon run size based on a model (SCMM) and mark-recapture estimates, weekly TAC, and weekly catch estimates from the District 108 gillnet, sport, subsistence, and troll fisheries and the Canadian gillnet and sport fisheries, 2007.

The preseason forecast for the terminal Stikine River large Chinook salmon run was approximately 37,500 fish (Table 1), which indicated a run size characterized as below average. Joint Canadian and U.S. inseason predictions of terminal run size ranged from 42,000 to 50,000 Chinook salmon (Table 1). Managers used the daily catch and effort data transmitted from the Kakwan Point tagging site to make daily run projections. Joint weekly run size estimates were calculated on Wednesday or Thursday in the current week and were used to set the following week's fishery openings. Managers used the model estimates in weeks 22-23 and the average run size generated by the weekly markrecapture and SCMM estimates after week 24 (10-16 June) to make weekly management plans. (note: In general, both U.S. and Canadian managers sensed that the inseason run
size estimates were affected by record high water levels.) All projections generated by the joint SCMM and the M-R study indicated a run size greater than the preseason expectation and the 2002-06 average. Based on M-R data from the inriver commercial fishery and stratified by weeks, the final postseason estimated terminal run size of Stikine Chinook salmon was 38,824 large Chinook salmon, below the final inseason estimate of 44,000 large Chinook salmon, and above preseason forecast of 37,500 large Chinook salmon (Table 1). The 2007 Little Tahltan escapement of 562 fish represents approximately $4 \%$ of the total inriver escapement of 14,559 fish, compared to the average of approximately $20 \%$.

## Sockeye Salmon

The SMM was updated to provide inseason projections of the Stikine River sockeye salmon run, including: the Tahltan stock (wild and planted combined); the planted Tuya stock; and the mainstem stocks. The model for 2007 was based on CPUE data from 1985 to 2006 from the Alaska District 106 fishery and the Canadian commercial fishery in the lower river and from 1986 to 2004 from the lower Stikine River test fishery. Linear regression was used to predict run size from cumulative CPUE for each week of the fisheries beginning in week 27 for District 106 and for the inriver fisheries. As in 19992006, the intercept was forced to be zero in order to correct for a tendency to overestimate the run size in the early weeks during years of low abundance. Each CPUE and run size data set is significantly correlated.

Initially in 2007 the inriver test fishery CPUE data was slated to be the primary source for generating inseason projections of sockeye salmon run size; however, the CPUE from the commercial fishery was used due to the extended fishery openings and resultant limited or absent test fishing activity. Calculations for the lower Stikine River commercial CPUE excluded catch and effort data from the Flood Glacier area, i.e., the area introduced in 1997 and fished through the 2000 season and again opened in 2004-2007. In addition, the annual weekly CPUE values were adjusted in order to make the current year data comparable with historical CPUE. For example, during 1979-1994 and 2000-2004, only one net per license was permitted, while in 1996-1999 and 2005-2007 two nets per license were allowed. It is estimated that the second net increased the catch and CPUE by approximately $25 \%$.

In 2007, the preseason forecasts were used during statistical weeks 24 (June 10-June 16) through 26 (June 24-June 30). After week 26, inseason forecasts of run size and TAC, produced by the SMM and CPUE data in the lower river commercial fishery, were used to determine weekly fishing plans (Table 2). The weekly inputs to the model included: the catch, effort and stock composition (proportion Tahltan/Tuya from egg diameters, proportion planted Tuya from thermal mark analyses of otoliths) in the Canadian lower river test (when in operation) and commercial fisheries; the upper river catch in the aboriginal fishery (AF) and upper river commercial fishery; the catch, effort and assumed stock composition in Subdistrict 106-41 (Sumner Strait); and, the catch and assumed stock composition in District 108 and Subdistrict 106-30 (Clarence Strait). Results of thermal mark analyses were available inseason for the marine and lower river fisheries to account for Tuya production in the model and reduce the risk of over-estimating the TAC
of Tahltan sockeye salmon. In 2007 the inriver commercial fishery CPUE was the primary forecast used. (The test fishery was not prosecuted until late July due to prolonged commercial fishery openings.)

Table 2. Weekly forecasts of run size and total allowable catch for Stikine River sockeye salmon as estimated inseason by the Stikine Management Model, 2007.

| Stat. <br> Week | Start <br> Date | Forecast Run Size | TAC |  |  | Cumulative Catches |  |

${ }^{\text {a }}$ Does not include test fishery catches
Initially, average stock proportions in District 106 and 108 catches, from historical postseason scale pattern analysis (SPA), were assumed for weekly catches; the averages used each week depended upon whether the run was judged to be below average, average, or above average. The Tuya and planted Tahltan stock proportions were subsequently adjusted inseason based on the analysis of otolith samples taken in Districts 106 and 108. The weekly estimate of Tuya fish in District 106-41 and 108 was added to the historical proportion of Tahltan fish in the SMM since this stock was not present in the historical database.

The preseason forecast for the Stikine River sockeye salmon run was 233,600 fish (Table 2), which indicated a run size characterized as an average run. The forecast included approximately 60,900 natural Tahltan sockeye salmon, 79,800 planted Tahltan fish, 28,200 planted Tuya sockeye salmon, and 64,700 mainstem fish. Canadian inseason predictions of total run ranged from 203,080 to 260,978 sockeye salmon; U.S. forecasts
ranged from 204,821 to 277,717 (Table 2).. All inseason forecasts indicated an above average run. Differences in U.S. and Canadian weekly predictions are due only to different catch data inputs being used for the updates. The SMM over predicted the run every week; the final inseason estimate was $28,000(14 \%)$ fish over the final postseason estimate (Table 2,3).

## U.S. Fisheries

The 2007 gillnet harvest in District 106 included 1,852 large Chinook, 92,481 sockeye, 80,573 coho, 383,355 pink and 297,998 chum salmon (Appendix A.1). Chinook and chum salmon harvests were above average, while the other salmon harvests were below average. The estimated contribution of Stikine River sockeye salmon to the District 106 sockeye salmon harvest was 37,856 fish or $41 \%$ of the harvest (Appendix A.2). An estimated 1,415 Chinook salmon in the District 106 harvest ( $76 \%$ ) were of Alaska hatchery origin (Appendix A.1). An estimated 34,158 coho salmon in the District 106 harvest were of Alaska hatchery origin, (42\%). The District 106 drift gillnet fishery was open for 49 days from June 10 through October 2 (Appendix A.1). This was above the average fishing time of 47 days. Sections 6-A, 6-B, and 6-C were open simultaneously each week throughout the season. Weekly fishing effort in number of vessels fishing in District 106 was below average for every week of the season with the exception of weeks 24 through 27. The greatest effort in vessels fishing, 78 boats, occurred in week 28. However, the greatest effort in boat days (304) occurred two weeks earlier in week 26 (Appendix A.1). The total season effort was 2,741 boat days (Appendix A.1).

The Sumner Strait fishery (Subdistricts 106-41 \& 42) harvested an estimated 36,720 Stikine River sockeye salmon (Appendix A.4), $51 \%$ of the sockeye salmon harvest. The Clarence Strait fishery (Subdistrict 106-30) harvested an estimated 1,136 Stikine River sockeye salmon (Appendix A.6), $6 \%$ of the sockeye salmon harvest.

In District 108, 14,627 large Chinook, 70,580 sockeye, 19,880 coho, and 39,872 pink and 177,547 chum salmon were harvested (Appendix A.7). Chinook, sockeye and chum salmon harvests were above average while coho and pink salmon harvests were below average. The District 108 fishery harvested an estimated 48,554 Stikine River sockeye salmon (Appendix A.8), $69 \%$ of the sockeye salmon harvest. The District 108 fishery started on May $7^{\text {th }}$ and included five weeks of directed Chinook salmon fishing before the usual sockeye salmon opening occurred in week 24 (June 10). District 108 closed concurrently with District 106 on October $2^{\text {nd }}$. The 56 days the district was open is above the average of 50 days (Appendix A.7). Excluding the directed Chinook salmon fishery, the district was open for 51 days, which is above average (this average only includes the usual sockeye salmon fishery in the 2005 and 2006 season). An estimated 40\% (7,992 fish) of the District 108 coho salmon harvest was of Alaskan hatchery origin (Appendix A.7). Alaska hatchery Chinook salmon contributed an estimated at 5,483 fish, $37 \%$ of the harvest. The weekly fishing effort in number of vessels fishing in District 108 during the usual fishery (weeks 24 through 40) was above average every week with the exception of weeks $25,28,37$, and 38 . The season effort of 2,625 boat- days, (weeks $24-40$ ) was above the average of 1,545 boat-days. The District 108 test fishery did not take place in 2007 (Appendix A.9).

a Escapement into terminal and spawning areas from traditional fisheries.
b Catch allowed in terminal areas under the Excess Salmon to Spawning Requirement license.
c Fish returning to the Tuya system are not able to access the lake where they originated due to velocity barriers.
d The number of Tuya fish that should be passed through traditional fisheries in order to harvest the Tuya stock at the same rate as the Tahltan stock to ensure adequate spawning escapement for Tahltan fish.
e Includes traditional, ESSR, and test fishery catches.
f Does not include ESSR or test fishery catches.
g U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than in the listed fisheries.

The 2007 season was the fourth season a U.S. Federal subsistence sockeye salmon fishery was conducted on the Stikine River, and was the third season that U.S. Federal subsistence Chinook and coho salmon fisheries were conducted. The fisheries were managed by the United States Forest Service. A permit issued by the USFS to federally qualified users was required. The fisheries took place on the Stikine River upriver from marine waters to the U.S./Canadian border. Fishing in "clearwater" tributaries or side channels and at stock assessment sites was prohibited. The Guideline Harvest Levels for

Chinook, sockeye, and coho salmon were set at 125, 600, and 400 fish, respectively. The open dates were May 15 to June 20 for the Chinook salmon fishery, June 21 to July 31 for the sockeye salmon fishery, and August 15 to October 1 for the coho salmon fishery. The allowable gear for the fishery included dipnets, spears, gaffs, rod and reel, beach seine, and gillnets not exceeding 15 fathoms in length with mesh size no larger than $5 \frac{1}{2}$ inches except during the Chinook salmon fishery when mesh up to 8 inches was allowed. A total of 50 permits was issued and the estimated harvests included 37 Chinook, 245 sockeye, and 23 coho salmon.

Harvests in Districts 106 and 108 consist of species of mixed stock origin; the contribution of Stikine River stocks is estimated for sockeye salmon in each district, and the Stikine River Chinook salmon contribution is estimated in District 108. The proportions of Stikine River sockeye salmon in the District 106 and 108 harvests were estimated inseason using both the historical proportions of each stock and the inseason proportions of thermally marked fish from fry plants to Tahltan and Tuya Lakes. The proportions of Stikine River Chinook salmon were estimated by subtracting the hatchery contributions deduced from port sampling efforts.

The third consecutive commercial directed Stikine River Chinook salmon drift gillnet fishery in recent years occurred in weeks 19 through 23 of the 2007 season. The preseason forecast was considerably smaller in comparison to the 2005 and 2006 seasons. The total run was predicted to be 37,000 adult Chinook salmon for 2007. The U.S. total allowable catch based on this forecast was approximately 6,100 fish (not including the base level catch). The fishery was limited to the waters in District 108 in order to target adult Stikine Chinook salmon. The 2007 directed Stikine Chinook salmon fishery openings reflected decisions made on several issues among commercial and sport groups by the Stikine King Salmon Workgroup previous to the 2006 season. In 2007, 104 gillnetters made landings of Chinook salmon over the course of the five-week fishery. A total of five days were fished within this time period.

The gillnet fleet harvested the bulk of the Stikine large Chinook salmon in District 108 with an estimated 9,099 fish caught through week 29 . The sport fishery was open continuously from week 18 through 29 with liberalized bag and gear limits. The sport fishery harvested an estimated 3,273 Stikine large Chinook salmon during this time period. The troll fishery had three-day openings throughout most of District 108 from week 19 through 23 . In weeks 24 through 26 , the troll fishery switched to five-day openings as the gillnet openings became more liberal. The spring troll fishery was closed by regulation on June 30. The troll fishery accounted for 1,346 Stikine Chinook salmon in District 108. The final cumulative U.S. harvest of large Stikine Chinook salmon through week 29, including the federal Stikine subsistence fishery, was 13,755 fish. The final postseason estimate of the total terminal run was 38,824 large Chinook salmon and was based upon mark-recapture information. Based upon that final postseason estimate of the run size, the U.S. allowable catch was 10,424 large Stikine Chinook salmon (not including the base level catch).

The District 108 directed Stikine Chinook salmon gillnet fishery began at 8:00 am on Monday, May 7 (week 19) for a 24 -hour period. This short opening was influenced by a relatively small preseason forecast. The small forecast also led to the closure of the Stikine River flats in District 108. Small area closures were used to reduce conflicts between commercial and sport fishers and for steelhead conservation. Several of the 2007 season area closures were dependent on the weekly openings of the gillnet fishery, and the reduced, one-day openings that occurred each week of the directed Stikine Chinook salmon fishery resulted in few area closures. A minimum mesh size of 7 inches for gillnetters throughout the directed Stikine Chinook salmon fishery was instituted in 2006 and continued in 2007 for steelhead conservation. Thirty-seven gillnetters made landings in District 108 during the initial opening; additional boats fished but had no harvest. The majority of boats fished in Section $8-B$, and this trend remained throughout the directed Chinook fishery. A unique dynamic of the fishery was the proximity to town; most fishers did not spend entire openings without returning to port. The gillnet catch rates in the initial opening were similar to the previous two years and suggested a strong run. The first inseason run estimate was not released until week 21; therefore the preseason forecast was used for the first three weeks of the directed Stikine Chinook salmon fishery. The estimated District 108 gillnet harvest for week 19 was 250 large Chinook salmon. The US weekly TAC guideline, based on historical run timing and the preseason forecast, was approximately 500 Stikine Chinook salmon. After including troll and sport fish harvests, and deducting the hatchery component, the total US harvest was slightly above the weekly guideline.

During weeks 20 (May 13 - May 19) and 21 (May 20 - May 26), District 108 was opened with the same area and time as in week 19 . Gillnet effort increased steadily as the season progressed with 52 boats making landings in week 20 and 76 boats in week 21 . The effort in both week 20 and 21 was similar to that seen in the respective weeks of the 2005 season. The cumulative harvest of large Stikine Chinook salmon by the U.S. fisheries was estimated at 3,500 fish by the end of week 21 . Although weekly allowable catches had been exceeded during these openings, the run appeared strong based on both the commercial marine catches and the inriver tagging rates. In the middle of week 21 , the first inseason forecast indicated a terminal run size up to 48,000 fish. The U.S. TAC increased to over 13,000 adult Stikine Chinook salmon, almost double the 7,000 fish TAC from the preseason forecast.

During weeks 22 (May 27- June 2) and 23 (June 3 - June 9), openings were again restricted to 24 hours with an area closure for the Stikine River flats. The week 22 opening began on Tuesday, May 29 instead of the traditional Monday opening due to the Memorial Day holiday. Although the terminal run and resulting TAC had jumped up substantially from the preseason forecast, the anticipated increase in effort combined with extrapolated catch rates from the previous two seasons (which had been tracking nearly identical to this season) resulted in conservative one-day openings. Gillnet effort during the directed Chinook salmon fishery peaked during in weeks 22 and 23 with 83 and 86 boats participating, respectively. The estimated US harvest of Stikine Chinook salmon in week 22 was 1,900 fish and in week 23 was 2,050 fish. The terminal run forecast dropped in week 22 to 44,000 fish. The total US Stikine Chinook salmon harvest was below the
weekly TAC guideline in week 22 and was nearly identical to the guideline in week 23 . The estimated cumulative harvest by all U.S. fisheries was approximately 8,400 adult Stikine Chinook salmon by the end of week 23. The terminal run forecast remained at 44,000 fish in week 23 . The corresponding U.S. TAC at this point was approximately 10,650 fish. Signs of a strong Stikine run remained evident in the gillnet fishery as weekly catch rates remained very similar to the 2005 and 2006 seasons. The week 23 opening was the last opening directed at Stikine Chinook salmon; the sockeye salmon management regime started in week 24.

The District 106 gillnet season began, and the District 108 season continued into sockeye salmon management, at 12:00 noon on Sunday, June 10 (week 24) for a two-day period. In District 108, the Stikine River flats remained closed in part due to high Stikine water levels and the possibility that fish could potentially be pushed back out of the river. However, there was no sign of a higher than normal occurrence of dark or water-marked Chinook salmon during the weekly survey. The majority of gillnetters that fished in District 108 kept their Chinook salmon gear on because catch rates had been building in the previous weeks. The highest effort of the season in District 108 occurred in week 24 with 87 boats fishing (Appendices A. 3 and A.5). High catch rates in week 24 resulted in the largest weekly harvest of Chinook salmon in District 108 for the season as was the case in the previous two seasons. The total US Stikine Chinook salmon harvest in week 24 was 4,300 fish and the weekly TAC guideline was 2,400 fish. The hatchery Chinook salmon contributed nearly one-quarter of the gillnet harvest. The terminal run forecast increased to just under 50,000 Stikine Chinook salmon resulting in a US TAC of 14,500 fish. The cumulative US harvest through week 24 was 12,700 Stikine Chinook salmon. The first sockeye salmon opening is normally two days and any decision to extend fishing is based on fishery harvest rates estimated by management biologists on site in the fishery. This season was similar to last season in that the vast majority of boats in District 108 were targeting Chinook salmon so the sockeye salmon catch rates were not very informative. However, a larger than expected number of sockeye salmon were being caught in Chinook salmon gear (mesh size 7 inches or greater). The sockeye salmon catch rates in District 106 were high for the 13 boats that made landings from the district. Only one boat fished in Clarence Strait (106-30) for this initial sockeye salmon opening. The inseason otolith readings for sub-district 106-41 indicated that $34 \%$ of the catch was comprised of thermally marked Tahltan fish while $15 \%$ of the catch was comprised of marked Tuya fish. The District 108 readings indicated $46 \%$ thermally marked Tahltan fish and $12 \%$ thermally marked Tuya fish. The preseason SMM forecasted a total Stikine River TAC of 172,805 fish and a Tahltan TAC of 115,517 fish (Table 2). This would allow the U.S. fisheries to harvest a total of 86,402 Stikine River fish, including 57,758 Tahltan fish. The preseason forecast was used for weeks 24-27, while the inriver commercial fishery CPUE was used for the remainder of the sockeye salmon season.

During week 25 (June 17-June 23), there were 48 boats fishing in Sumner Strait, 10 boats fishing in Clarence Strait and 40 boats fishing in District 108 (Appendices A. 3 and A.5). A substantial closure line was implemented in District 108 to move the fishing effort far off the mouth of the Stikine River due to concerns based on the Chinook salmon harvest sharing agreement. The gillnet harvest this week was estimated to be 1,000 Chinook
salmon. The Stikine Chinook salmon forecast increased slightly to 50,000 fish, the highest forecast of the season. The cumulative US Stikine Chinook salmon harvest through week 25 was 13,600 fish. Both districts were open for an initial three days, and due to high sockeye salmon catch rates, both districts were extended for an additional two days. Many boats that started with Chinook salmon gear in District 108 switched over to sockeye salmon gear early in the opening. The sockeye salmon catch rates in District 106 and 108 were both substantially above average.

During week 26 (June 24-June 30), there were 61 boats fishing in Sumner Strait, 15 boats fishing in Clarence Strait and 69 boats fishing in District 108 (Appendices A. 3 and A.5). With substantial sockeye salmon catches last week indicating a strong Tahltan run, the District 108 closure was relaxed back to the Stikine flats. Both districts were opened for an initial four days and with continued above-average sockeye salmon catch rates, District 108 was re-opened for a 24 -hour midweek. The inseason otolith readings for subdistrict $106-41$ for week 26 indicated that $28 \%$ of the catch was comprised of thermally marked Tahltan fish while $16 \%$ were thermally marked Tuya fish. The District 108 readings indicated $35 \%$ thermally marked Tahltan fish and $19 \%$ thermally marked Tuya fish. The estimated U.S. total Tahltan sockeye salmon harvest by the end of this week was approximately 36,000 fish.

During week 27 (July 1-July 7), District 106 and 108 were opened for an initial three days (Appendix A.7). There were 21 boats fishing in Clarence Strait and 55 boats in Sumner Strait, and a total of 78 boats fishing in District 108 for the week (Appendices A.3, A.5, and A.7). Surveys on the fishing grounds showed that the District 108 sockeye salmon catch rates continued to be above average but the District 106 catch rates were below average. The effort dropped off substantially toward the end of the opening due to poor weather, the $4^{\text {th }}$ of July holiday, and slower catch rates in District 106. A 24-hour mid-week opening was announced in District 108 due to above average catch rates and low effort. The percentage of thermally marked Tahltan sockeye salmon in sub-district 106-41 dropped to $20 \%$ while the marked Tuya fish contributed 13\%. In District 108, marked Tahltan fish contributed $31 \%$ while marked Tuya fish contributed $22 \%$. The first inseason forecast came out towards the end of this week. The total Stikine sockeye salmon TAC increased to 216,689 fish with a total Tahltan TAC of 159,345 fish. This resulted in a US TAC of 79,672 Tahltan sockeye salmon. The estimated cumulative U.S. harvest of Tahltan sockeye salmon in District 108 was 23,054 fish while an estimated 24,506 Tahltan fish were harvested in District 106 for a total U.S. Tahltan sockeye salmon harvest of 47,560 fish through week 27 . The mainstem forecast dropped from a preseason total run prediction of 67,000 fish to 54,967 fish.

During week 28 (July 8-July 14), 78 boats fished in District 106 and 67 boats fished in District 108 (Appendices A. 1 and A.7). Both districts were open for an initial three days of fishing time. Fishing ground surveys indicated that sockeye salmon CPUE for the three-day opening was below average in District 106 and near average in District 108. A shift in effort in District 108 occurred this week with several boats heading to the southern part of the district to target the Anita Bay chum salmon run. No extra time was announced this week due to decreased sockeye salmon catch rates. The inseason otolith
readings for week 28 indicated that the marked Tahltan fish contributed $13 \%$ of the District 106 catch and $39 \%$ of the District 108 catch. The marked Tuya fish contributed $3 \%$ and $18 \%$ in District 106 and 108 respectively. The current forecast from the SMM dropped slightly from the week before. The SMM run prediction decreased the Tahltan component to 171,762 fish, with a TAC of 146,679 fish. The estimated U.S. Tahltan harvest by the end of this week was 59,854 sockeye salmon with a U.S. TAC of 73,339 fish. The estimated U.S. harvest of mainstem sockeye salmon was 7,882 fish with a U.S. TAC of 4,662 fish. It was generally believed that once again the SMM was under forecasting the mainstem run size, as was the case the last couple of years, due to the Tahltan sockeye salmon run being stronger than normal. Another complicating factor that had been chronic this season was sustained high water levels on the river. The inriver sockeye salmon fishery in both weeks 28 and 29 occurred during very high water levels.

During week 29 (July 15-July 21), there were 77 boats fishing in District 106 and 61 boats fishing in District 108 (Appendices A. 1 and A.7). Both districts were open for an initial three days. The majority of fishers in District 108 switched to larger gear to target chum salmon and were fishing in the far southern reaches of the district. The sockeye salmon catch rates for the small amount of boats that were actually targeting sockeye salmon in District 108 were above average. Due to below-average sockeye salmon catch rates throughout the entirety of District 106 and 108 and the decreasing forecast, no extra time was warranted in either district. The U.S. catch of Tahltan sockeye salmon through week 29 was estimated at 65,022 fish with a U.S. TAC of 62,218 fish. The inseason otolith readings for week 29 indicated that marked Tahltan fish contributed to $2 \%$ of the District 106 catch and $19 \%$ of the District 108 catch. The SMM estimated a total U.S. mainstem catch of 9,961 sockeye salmon with a remaining U.S. TAC of 3,578 fish. The percent Tahltan/Tuya fish in the lower river commercial fishery remained high this week $(92 \%)$. With little effort directed at sockeye salmon in District 108 and average catch rates for boats targeting sockeye salmon, a reduced opening was announced for the following week.

During week 30 (July 22-July 28), there were 60 boats fishing in District 106 and 63 boats fishing in District 108. Both districts were open for an initial two days. The reduced opening was due to concern for McDonald Lake sockeye salmon as well as concerns over the Stikine sockeye salmon harvest sharing agreement. Catch rates in both districts were below average on the whole. However, the sockeye salmon catch rates for those few boats that were targeting sockeye salmon in District 108 were again above average. Although the mainstem run did not appear strong, it was apparent that the SMM was overestimating the U.S. mainstem catch. No additional time was warranted in either district this week. The U.S. catch of Tahltan sockeye salmon was estimated at 66,378 fish with a U.S. TAC of 58,610 fish. The SMM estimated a total U.S. mainstem catch of 11,781 fish with a U.S. remaining TAC of 1,518 fish. Interestingly, the marked Tahltan proportion increased to $12 \%$ in District 106 this week while dropping to $15 \%$ in District 108. Again, with reduced effort for sockeye salmon and above average catch rates for those boats targeting sockeye salmon in District 108, a reduced opening was announced for the following week.

During week 31 (July 29-August 4), there were 32 boats fishing in District 106 and 60 boats fishing in District 108. Both districts were opened for an initial two days. Again, the reduced opening reflected concerns for McDonald Lake sockeye salmon and the Stikine harvest sharing agreement. A substantial closure in District 106 was implemented this week for McDonald Lake sockeye salmon conservation efforts. The majority of Sumner Strait in District 106 was closed for the entire opening. Sockeye salmon catch rates in both districts were below average, but similar to the previous week, the sockeye salmon catch rates in District 108 were not a true reflection of run strength due to the shift in effort to target chum salmon. Again, the small number of boats targeting sockeye salmon in District 108 had above-average catch rates. Inriver indicators suggested that the egg ratio in the commercial catch was $50 \%$ Tahltan/Tuya. The current SMM run estimated that the mainstem component was increasing but only slightly. Once again, no additional fishing time in either district was warranted. The SMM estimated a U.S. harvest of 70,536 Tahltan sockeye salmon with a U.S. TAC of 60,419 fish (Table 1). The mainstem harvest by the U.S. was estimated to be 14,000 sockeye salmon with a remaining U.S. TAC of 3,010 fish. The inseason otolith readings for week 31 indicated that marked Tahltan fish contributed to $11 \%$ of the District 108 catch. The following week would be the last opening under the sockeye salmon management regime.

During week 32 (August 5-August 11), there were 31 boats fishing in District 106 and 54 boats fishing in District 108. Both districts were opened for an initial two days. This would be the last week of McDonald Lake sockeye salmon conservation efforts. Catch rates were below average in both districts but those boats targeting sockeye salmon in District 108 had average catch rates. Pink salmon were beginning to flood both districts, and management decisions were shifting to pink salmon abundance. However, no initial time was warranted during this last week of sockeye salmon management. The final inseason SMM run, released in week 36, estimated a total U.S. catch of 100,389 Stikine sockeye salmon broken into 66,943 Tahltan fish, 18,685 Tuya fish, and 14,761 mainstem fish. The US TAC for each component was 59,238 Tahltan fish, 12,925 Tuya fish, and 9,484 mainstem fish.

During weeks 33 through 35, both Districts 106 and 108 were managed for pink salmon. Both districts were open four days a week during this period. Section D of District 106 was closed from week 32 through week 35 . Good runs of pink salmon throughout this time period resulted in above-average gillnet openings. Pink salmon harvests in both districts are not always a true reflection of abundance because low prices for pink salmon and catches of other more valuable species may affect the fishing patterns and methods. During the 2007 season, the fishing effort was substantially less than average in District 106, however, in District 108 the effort was generally well above average for this time period. The anticipated hatchery chum salmon runs in District 108 were the catalyst behind the increased effort in the district at this time. Pink salmon harvests were below average in both districts.

Coho salmon management typically commences in late August or early September in both the District 106 and 108 gillnet fisheries. During week 36 (September 2 - September 8) the management emphasis changed from pink to coho salmon. Prior to the change to
coho salmon management the District 106 fishery harvested 46,084 coho salmon, approximately $57 \%$ of the total District 106 coho salmon catch. The Alaska coho salmon hatchery contribution to the District 106 fishery was below average every week of the season with the exception of weeks 25,26 , and 38 . Coho salmon catch rates mirrored the hatchery contribution in District 106 and were above average only during these same weeks. In District 108, a similar trend was seen later and coho salmon catch rates were above average only in weeks 27,28 , and 39 . The Fall coho salmon run in both districts was generally below average. Both districts had three two-day openings in weeks 36 through 38 , followed by a three-day opening in week 39 , and finally two days in week 40. The 2007 gillnet season in both districts ended at noon on Tuesday, October $2^{\text {nd }}$.

## Canadian Fisheries

Final catches from the combined Canadian commercial and aboriginal gillnet fisheries, and sport fishery in the Stikine River in 2007 included: 10,505 large Chinook, 60,013 sockeye, and 52 coho salmon. Chum and pink salmon were not retained. (Appendices A. 12 - A.16). There was no harvest in the terminal fishery located at the mouth of the Tuya River (Table 3). Because of the recently established targeted Chinook salmon commercial fishery, the catches of large Chinook salmon were well above average and the third highest on record. Catches of jack Chinook salmon were also well above average. The sockeye salmon catch was slightly above average. The final estimate of the total contribution of sockeye salmon from the Canada/U.S. fry-planting program to the combined Canadian aboriginal and commercial fisheries was 30,019 fish, $50 \%$ of the catch (Table 3).

A sockeye salmon test fishery was conducted for stock assessment purposes in the lower Stikine River from 27 July to 24 August, 2007. The test fishery was located immediately upstream from the Canada/U.S. border. Test fishery catches totaled: 1,108 sockeye, 188 coho, 327 pink, 64 chum salmon, and 18 steelhead trout (all steelhead trout, chum and pink salmon were released) (Appendices A.17, A.18). The objectives of the sockeye salmon test fishery were similar to those in previous years: to provide inseason catch, stock ID and effort data for input into the SMM to estimate the inriver run size; and, to determine migratory timing and stock composition of the sockeye salmon run for use in the postseason estimations of the inriver sockeye salmon run. Unfortunately, no sockeye salmon test fishing was conducted during most of July due to the prolonged commercial fishery openings. Proxy test fishery catches and CPUE for July were calculated based on the performance of the commercial fishery and the historical co-relation between commercial and test CPUE, 1996-04. Funding to conduct a coho salmon test fishery was not granted in 2007.

## Lower Stikine River Commercial Fishery

Canadian commercial fishers in the lower Stikine River harvested 10,131 large Chinook, 56,913 sockeye, and 50 coho salmon in 2007 (Appendix A.12). All pink and chum salmon and steelhead trout were released. The sockeye salmon catch above average. The catch of large Chinook salmon in the third year of the new, targeted fishery was third
highest on record. The catch of jack salmon was above average, while the catch of coho salmon was below average.

The stock composition of the lower river sockeye salmon catch (Table 3), was as follows: 18,266 planted Tahltan fish, which accounted for $32 \%$ of the sockeye salmon catch; 17,901 wild Tahltan fish accounting for $32 \%$ of the catch; 9,855 mainstem fish accounting for $17 \%$ of the catch; and 10,891 planted Tuya fish which accounted for $19 \%$ of the catch.

Stock compositions of the commercial catch taken in the targeted Chinook and coho salmon fisheries are not available. However, assuming that the Chinook salmon catch reflects the contribution of the Little Tahltan and 'other' stocks to the total inriver escapement, the commercial catch of Chinook salmon of Little Tahltan origin was 562 large Chinook salmon, the catch of large Chinook salmon originating from 'other' stocks was 13,997 fish.

Weekly Chinook and sockeye salmon guideline harvests, based on SCMM and SMM forecasts of the total allowable catch (TAC) apportioned by average run timing and domestic and international allocation agreements, were developed each week to guide management decisions during the Chinook and sockeye salmon seasons. For purposes of managing the lower river catch, 1,100 large Chinook salmon were allocated to the upper Stikine fisheries: 150, 50, and 900 large Chinook salmon in the sport, upper commercial and Aboriginal fishery, respectively. A total of 8,000 sockeye salmon was allocated to the upper Stikine commercial and aboriginal fishery. The remaining balance of the Chinook and sockeye salmon TAC was allocated to the lower Stikine commercial fishery. Particular attention was directed at weekly Chinook salmon guideline harvests and the inriver run and escapement projections of the various sockeye salmon stock groupings. Management through week 25 (June 17-June 23) was focused primarily on the harvest of large Chinook salmon. From week 26 through week 30, management emphasis switched to the Tahltan and Tuya Lake sockeye salmon stock after which time the sole focus was the management of mainstem sockeye salmon stocks through the end of the fishery week 32. A coho salmon management regime was not required in 2007 due to lack of commercial fishing effort on this species.

The Chinook salmon fishery commenced at noon May 06 (week 19) for a scheduled opening of two days. Fishers were limited to two nets with a maximum length of 135 meters. The maximum mesh size was 203 mm . Only one of the two nets was permitted to be deployed as a drift gillnet. The upper boundary of the fishing zone extended to a point near the confluence of the Porcupine and Stikine rivers. The opening was based on a preseason Canadian guideline harvest for week 19 of 162 large Chinook salmon. Water levels were extremely low in concert with an unusually abundant amount of ice flow. Fishing success was marginal with a total catch of 77 fish. The fishery was held at two days. Fishers faced major logistic challenges as a result of the extremely high snow pack that accumulated over the winter of 2007. A large amount of snow remained in the lower Stikine throughout May and early June. Some fishers sustained major property damage as a result of the snow loads and slides.

The fishery was posted for two days in week 20 (May 13-May 19) with a weekly target of 412 large Chinook salmon. Day one catches indicated that a one day extension was warranted in order to harvest the weekly quota. Day two and three catches improved beyond expectations. The fishery was held at three days with a catch of 593 fish, 181 fish over this week's quota. The cumulative catch per hour registered at the Kakwan tagging site, under good fishing conditions, was $\sim 30 \%$ below the 97-06 average. The river level started to rise mid week. (In light of the extreme snow pack remaining throughout the drainage, major water flows were anticipated throughout the course of the fishery.)

The fishery was posted for two days in week 21 (May 20-May 26) with a weekly target of $\sim 350$ large Chinook salmon. The preseason run size estimate of 37,500 remained as the governing run size for this week even though latitude was given to the managers to generate an inseason run size before May 25 as agreed to in the preseason management plan. Both US and Canadian managers reasoned there was no compelling inseason information that warranted an inseason estimate before the agreed to date. The water level increased this week to above seasonal average. The catch of 525 large Chinook salmon was better than expected and $\sim 170$ fish over the weekly quota. The fishery was held at two days. The catches at Kakwan Point tagging site remained below average. The U.S. cumulative CPUE in District 8 gillnet fishery was below, while the Canadian commercial CPUE close to average. A model estimate of 48,000 was generated on Thursday of the current week and will governed week 22 opening.

The fishery was posted for two days in week 22 (may 27-June 2) with a weekly target of $\sim 1,175$ large Chinook salmon and a projected run size of 48,000 Chinook salmon. The water level continued to rise early in the week, but crested at mid-week. The fishing conditions, therefore, were characterized as fair to good. Day one catches were low which prompted an extension in order to meet the weekly target. After three days of fishing with only a third of the weekly quota harvested it was decided to extend another two days. The total fishing time of six days yielded a catch of 782 large Chinook salmon, 400 fish below the weekly quota. A new model estimate of 44,000 Chinook salmon was generated and will serve to govern week 23 fishery. Kakwan catches are well below average. The U.S. cumulative CPUE in the District 8 gillnet fishery continued to be below the 2005-06 average. The Canadian commercial CPUE followed suit and was $\sim 20 \%$ below average.

The fishery was posted for three days in week 23 (June 3-June 9) with a weekly target of $\sim 1,100$ large Chinook salmon and a projected run size of 44,000 Chinook salmon. Day one catches indicated that an extension was warranted. A two day extension was granted. As the week progressed the water level rose dramatically and registered record seasonal flows (USGS water gauge 1976-07). The fishing conditions were very poor and the fishery was thus held at four days. There was little fishing activity conducted on day four. The total catch this week was 193 large Chinook salmon, well below the weekly quota of 1,100 fish.

The cumulative CPUE at the Kakwan Point tagging site was $\sim 70 \%$ below average. The low exploitation rate at the tagging site and the Canadian commercial fishery was
assumed to be negatively affected by the high water levels and possible the paucity fish. (Tagging operations ceased from 07-10 June due to high water and the inherent associated dangers. DFO field staff was on flood alert). The US weekly and cumulative CPUE remained below average this week as did the Canadian CPUE. The run size estimate of 44,000 fish did not change this week and will be used to govern the week 24 fishery. There was a high level of uncertainly and discussion in assessing run size for this week due to flood conditions which rendered assessment difficult.

In week 24 (June 10-June 16) the fishery was postponed one day due to high river levels. On Monday noon the fishery was opened for an initial three-day period. The weekly TAC was $\sim 1,600$ fish with a projected run size of 44,000 Chinook salmon. Catches reported after day two indicated a fairly liberal extension was warranted, therefore, the fishery was extended three days. Further, the commercial fishing zone was extended upstream $\sim 24 \mathrm{~km}$ to the mouth of the Flood River. (note: none of the fleet fished the newly opened upper zone this week.) Water levels dropped throughout the week which normally results in an improved exploitation rate. Day four saw improved catches, but overall the CPUE was below the 2005-06 average. The final catch for six days of fishing was 1,035 large Chinook salmon, almost 600 fish below the weekly allocation. The District 108 catch and CPUE were well above average and increased from week 23, when the fishery CPUE peaked in 2005-06. This observation indicated that the run was at least one week late and would presumably enter the river one week later than normal. (The possibility of fish milling in District 108 as a result of the record spring flows was discussed with the US manager). Run timing and run size estimates reflected a late run timing commencing week 25. The cumulative Kakwan Point CPUE was $\sim 70 \%$ below average; the Canadian commercial CPUE was $\sim 40 \%$ below average. A new run size estimate of 50,000 fish, based on late run timing, was generated on Thursday of week 24. The new estimate was used to govern week 25 fishery.

The fishery was posted for three days in week 25 (June 17-June 23) with a weekly target of $\sim 2,900$ large Chinook salmon and a projected run size of 50,000 Chinook salmon. Day two and three catches resulted in a decision to extend the fishery an additional two days. After day three with a cumulative catch of 750 large Chinook salmon, $25 \%$ of the weekly goal, the fishery was extended another two days. The seven day fishery in week 25 yielded a catch of $\sim 2,300$ fish, 600 fish short of the weekly goal. The water level dropped rapidly throughout the week, but was still above the seasonal average. The US catch and CPUE dropped dramatically this week as a result of area restrictions and presumably Chinook salmon run timing. The Canadian CPUE was below the 2005-06 average as was the Kakwan Point cumulative CPUE. An inseason run size estimate of 50,000 large Chinook salmon was generated (based on the average run size generated by the model and mark-recapture) and was used to govern the following week's fishery in concert with a sockeye salmon management regime. The preseason run timing curved indicated that the Chinook salmon run would peak in week 25. The inseason data, however, indicated that the run was a least one week late and should peak in week 26, in tandem with a predicted strong sockeye salmon run. A few of the Canadian boats experimented with sockeye salmon gear throughout the course of the week's fishery. The sockeye salmon catch was $\sim 400$ fish, above seasonal averages for the week. Record sockeye salmon
catches, which were four times average, were reported in District 106 and 108. The Canadian fleet was expected, therefore, to switch exclusively to sockeye salmon gear the following week

In week 26 (June 24-June 30) the fishery was initially opened for three days with management emphasis on both Chinook and sockeye salmon. The majority of the fleet switched to sockeye salmon gear; one boat fished the upper zone near the mouth of the Flood river. The Chinook salmon weekly quota, based on the model and m-r run size of 50,000 Chinook salmon, was $\sim 1,800$ fish; however, in light of the high water and late run timing, the catch shortage of 600 fish from week 25 quota was added to this week's quota for a total target catch of $\sim 2,400$ Chinook salmon. Sockeye and Chinook salmon catches were strong after two days of fishing. The fishery was, therefore, extended an additional three days. A further one day extension was granted after assessing the catch after five days of fishing. The total harvest for the week's seven day fishery was 2,400 Chinook and 12,500 sockeye salmon (most of which were Tahltan origin fish). The Chinook salmon catch was within the weekly quota. The sockeye salmon catch was over quota by approximately 4,000 fish based on average run timing and the preseason estimated run size of 233,500 sockeye salmon. The record sockeye salmon catches in both U.S. Districts 106 and 108 harvest in week 25 and the above average final catches reported this week, however, indicated that there was a high probability that the inseason run size estimate would exceed the preseason forecast. It was assumed that the Canadian catch for this week would, therefore, be within the acceptable weekly harvest guidelines once the inseason estimate was generated. River flows increased midway through the opening, yet the sockeye and Chinook salmon CPUE remained well above average. The CPUE at the Kakwan Point tagging site improved this week, but still was below the seasonal average. Catches of Chinook salmon in the First Nations fishery were weak and well below average. (Note: due to high water conditions the installation of the Little Tahltan Chinook salmon weir was delayed. It was operational on 27 June.) The U.S. lifted its District 108 area restriction which was implemented in week 25 in order minimize Chinook salmon interceptions.

In week 27 (July 1-july 7) the fishery was posted for an initial opening of five days. The primary management objective switched to sockeye salmon this week. The first model estimate of the season projected a run size of 261,000 sockeye salmon with a weekly guideline harvest of 19,000 fish. After four days of fishing and a catch of 8,000 sockeye salmon, the fishery was extended two days. The final catch was 16,500 sockeye and 1,300 Chinook salmon. Canada was over the weekly Chinook salmon guideline but below the weekly sockeye salmon quota. Daily otolith, scale, and egg diameter samples were collected commencing in week 25 . The data showed a high portion of Tahltan Lake sockeye salmon. The total catch of 16,500 sockeye salmon was comprised of 12,500 Tahltan Lake, 2,500 Tuya Lake, and 400 mainstem fish. The sockeye salmon CPUE waned as the week progressed, which caused some concern in regards to the initial indications that the run was returning in numbers well above expectations. Further, initial catch reports from US Districts 106 and 108 for week 27 indicate the run strength had weakened considerably and that the sockeye salmon run may have arrived early and in a truncated fashion. The US was alerted to their catch to date which appeared to show,
from Canada's perspective, they were over there cumulative weekly quota. In light of the model run size and the US catch, Canada was concerned about the mid-week extension that was granted to District 108 fishers.

In week 28 (July 8-July 15) the fishery opened for three days. The initial run size estimate this week was $\sim 261,000$ sockeye salmon with a weekly guideline harvest of $\sim 23,500$ fish. (The US model estimate was $\sim 277,000$ sockeye salmon.) The run estimate dropped to $\sim 240,000$ mid week. Day one catches and CPUE were well below average under very good fishing conditions. Day two CPUE remained below the seasonal average. The water level once again increased commencing in day two and proceeded to rise to seasonal records through the course of the fishery. Notwithstanding the 23,500 guideline harvest, and in light of the poor catches reported in District 106 and 108, which indicated that the run may have been weaker than the model estimate indicated, the fishery was held at three days. (note: the initial, preliminary catch for District 108 was 5,500 fish; the final week 27 catch estimate reported to Canada in week 28 was $\sim 14,000$ sockeye salmon). The total catch after three days of fishing was $\sim 3,500$ sockeye and $\sim 350$ Chinook salmon. The sockeye salmon catch was well below the weekly allocation of ~23,500 fish and consisted of 2,600 Tahltan Lake, 405 Tuya Lake, and 364 mainstem fish. The Chinook salmon harvest caught incidentally during the sockeye salmon fishery was over the weekly quota. The Chinook salmon run size based on averaging the m-r and model estimate decreased to 42,000 large fish. (The Kakwan tagging projected concluded on 10 July). Sockeye salmon had not yet arrived at Tahltan Lake. On average the Tahltan sockeye salmon arrive at the lake around 11 July. The First Nations catches were below seasonal averages, which may be due to poor gear efficiency caused by high water in concert with the late arrival of the stock.

In week 29 (July 16-July 21) the fishery was opened for an initial three day period. The model indicated a run size of $\sim 240,000$ fish and a guideline harvest of 34,000 sockeye salmon. The model also indicated that the mainstem run was relatively weak with a total run size of 40,000 fish. The near record low inriver CPUE of mainstem sockeye salmon suggested that the mainstem estimate from the model may have overestimated the run strength. Based on the guideline harvest this week and the relatively low catches taken in days one and two, the fishery was extended two days. Catches in day four indicated that an additional two day opening was warranted. The water level was well above average for the duration of the week, but dropped rapidly through Friday, when it again rose in a rapid fashion. Both catches and CPUE were below average. The total catch taken during the seven day fishery was $\sim 8000$ sockeye salmon. The catch was composed of $\sim 5,000$ Tahltan Lake, $\sim 2,300$ Tuya Lake and $\sim 2,000$ mainstem fish. It was felt that the poor catches were due to both the relatively poor fishing conditions and the "shadow" effect from the US gillnet fisheries. The US manager was apprised of this and the fact that according to model estimate they had fished over their allocated amount. It was articulated by the US that most of the fleet targeted the projected 1.2 million chum salmon run to Anita Bay and that relatively few Stikine bound sockeye salmon were harvested. (total stat wk 29 catch was $\sim 5,000$ ). The inriver CPUE of mainstem fish was $80 \%$ below average. This stock grouping warranted fishing restrictions the following week. A new model estimate generated late in the week indicated that the run size
dropped to $\sim 215,000$ fish. The catch and CPUE of sockeye salmon in the First Nations fishery remained below seasonal averages. The Tahltan weir count was only one fish, while the average count for this date is 5,000 fish. The projected escapement based on the inriver model estimate, minus the catch and projected catch of Tahltan Lake sockeye salmon was $\sim 50,000$ fish. It was assumed, based on the major high water events that the sockeye salmon were late to both the lake and to the First Nations fishing grounds.

In week 30 (July 22-July 28) the fishery was opened for an initial three-day period. The model indicated a run size of $\sim 217,000$ fish and a guideline harvest of 25,300 sockeye salmon, primarily Tahltan Lake fish. Again the model also indicated that the mainstem run was relatively weak with a total run size of 38,000 fish. The veracity of the mainstem model estimate remained in question. It was obvious that the target catch would not be met in light of Tahltan Lake sockeye salmon run timing that showed, on average, over $80 \%$ of the Tahltan run transited the fishery by week 29 . The water level dropped dramatically throughout the week. Fishing conditions were good, but catches and CPUE were below average. The total catch was 4,100 sockeye salmon, 2,700 of which were of Tahltan Lake origin and approximately 610 were mainstem origin. Tuya origin sockeye salmon constituted the balance of the catch. The first coho salmon was harvested this week. The CPUE of the mainstem component increased slightly but was $70 \%$ below average. In light of the paucity of mainstem fish and the available Tahltan Lake sockeye salmon TAC the fishery was only extended two days. The Tahltan Lake weir count remained below average. The projected total escapement based on the weir count to date was 5,000 fish. The Tahltan River was flown in search of possible landslides that may have impeded or block Tahltan Lake bound fish. No barriers were observed, although several slides/sluffs along the bank of the river were identified. The sockeye salmon test fishery started on Friday of week 30. Catches were relatively strong with the Tahltan Lake component dominant in the catch.

In week 31 (July 29-August 4) the fishery opened for an initial three-day period. The model estimate dropped to 204,000 fish and continued to indicate a weak run of mainstem fish. Catches and CPUE were above average. The CPUE of mainstem fish was also above average, which prompted a two-day extension. The total sockeye salmon catch this week was 6,900 fish, 2,500 of which were of Tahltan Lake origin and approximately 3,700 were mainstem fish. Tuya origin fish constituted the balance of the catch. Overall the test CPUE (sockeye catch per drift) was above average. The CPUE of mainstem fish was also above average. Sockeye salmon counts at Tahltan Lake remained below average this week. The projected weir count, based on counts to date, was 17,000 fish. The projected weir counts based on the model estimate was for an escapement of $\sim 42,000$ fish to Tahltan Lake. The First Nations catches remain below seasonal averages. Most of the fishers concluded their fishing season this week.

In week 32 (August 5-august 11) the fishery opened for an initial three day period. A new model estimate ran after one day of fishing indicated that the run increased to $\sim 230,000$ sockeye salmon. The mainstem component increased to 53,000 fish, indicating that this stock group was late arriving to the river. Fishing conditions were fair to good. The water level dropped to below the seasonal average. Catches and CPUE were above seasonal
averages in all stock groupings. The CPUE of the mainstem component was a record high. Notwithstanding an available weekly quota, the fishery was held at three days. Approximately $50 \%$ of the fleet concluded their 2007 commercial fishing activity. The remaining fishers expended only light effort this week. The total catch was 2,500 sockeye salmon, 1,900 of which were of mainstem origin. Tuya and Tahltan Lake origin fish constituted the balance of the catch. A total of 41 coho salmon was also harvested this week. (Note: the fleet showed no indications of targeting coho salmon this year.) The cumulative sockeye salmon count at Tahltan Lake this week was $\sim 15,000$ fish. The First Nations catches and CPUE remain below seasonal averages.

In week 33 (August 12-August 18) the fishery opened for an initial three-day period. The model generated a run estimate of 225,000 sockeye salmon. The mainstem sockeye salmon component dropped to 50,000 . No commercial fishing activity was conducted. The 2007 season concluded for all lower commercial fishers. The sockeye salmon test fishery overall CPUE (sockeye catch per drift) was above average, with the bulk of catch consisting of mainstem sockeye salmon. The cumulative sockeye salmon count at Tahltan Lake this week was 18,500 fish. The First Nations fishery concluded this week.

In week 34 (August 19-August 25) the fishery was open through October 20. This action was taken in order to provide coho salmon fishing opportunities should any of the commercial fishers decided to fish. The sockeye salmon test fishery overall CPUE was above average, with the bulk of catch consisting of mainstem sockeye salmon. The test fishery ended on 24 August. The cumulative sockeye salmon count at Tahltan Lake this week was 20,200 fish. The projected escapement based on the most recent model estimate, minus the inriver catch, was $\sim 52,000$ sockeye salmon.

## Upper Stikine River Commercial Fishery

A small commercial fishery has existed near Telegraph Creek on the upper Stikine River since 1975. A total of 912 sockeye salmon was caught in 2007, which was above average (Appendix A. 14). Twenty-five jack and 10 large Chinook salmon were harvested. The jack Chinook salmon harvest was above average, while the harvest of large Chinook salmon was below average. The fishing effort was above average with 17 boat-days fished. Generally, fishery openings were based on the lower Stikine commercial fishery openings, lagged one week. The first opening, however, was concurrent with the lower fishery opening.

## Aboriginal Fishery

The Stikine River aboriginal fishery, which is located near Telegraph Creek, harvested 364 large Chinook, 233 jack Chinook, 2,188 sockeye, and 2 coho salmon (Appendix A. 15). The harvest of large Chinook and sockeye salmon were below average. The harvest of jack Chinook salmon was close to average. As in 2004-06, sockeye salmon were up to two weeks late arriving to the fishing grounds. It appears that the run was relatively protracted and did not exhibit a distinct peak in Week 29 as is the normal pattern. High water may have reduced harvest efficiency throughout the bulk of the fishery.

## Sport Fishery

The Stikine River salmon sport fishery targets primarily Chinook salmon and its principal fishing location is located at the mouth of the Tahltan River. Minor sport fishing activities occur in upper reaches of the Tahltan River and in some tributaries of the Iskut River, including Verrett and Craig River. The 2007 the catch estimate was zero fish. The zero catches were a product of very minor fishing effort in concert with extremely high water and relatively low abundance.

## Escapement

## Sockeye Salmon

A total of 21,074 sockeye salmon was counted through the Tahltan Lake weir in 2007; below average (Appendix A.19). The 2007 count was approximately $8 \%$ below the escapement goal of 24,000 , but within the escapement goal range of 18,000 to 30,000 fish. An estimated 8,966 fish ( $42 \%$ ) originated from the fry-planting program, which does not reflect $61 \%$ contribution of smolts observed in 2004, the principal cycle year contributing to the 2007 run. A total of 200 sockeye salmon was sacrificed at the weir for stock composition analysis. In addition, a total of 2,839 sockeye salmon was collected for broodstock, resulting in a spawning escapement of 18,035 sockeye salmon in Tahltan Lake. Based on the final inseason model estimate of 90,300 inriver Tahltan Lake sockeye salmon, minus the inriver catch of 38,500 , the escapement to Tahltan Lake was projected to be $\sim 51,000$ fish. Tahltan River was flown to assess for fish blockages in July. Tashoots Creek, draining Tahltan Lake, was also assessed for fish blockages. None was observed in either river.

The spawning escapements for the non-Tahltan and the Tuya stock groups are calculated using stock ID, test fishery and inriver catch data. Because the commercial fishing activity concluded before the run terminated (last fishing was in week 33), egg diameters from the test fishery were used for stock composition estimates for the last weeks of the sockeye run. A proxy CPUE was used for these same weeks based on a linear regression of District 108 CPUE of Stikine fish vs. inriver commercial CPUE with intercept forced to zero ( $\mathrm{R}^{2}=.71$ ). Based on this run reconstruction approach, the final escapement estimates are 20,865 non-Tahltan and 7,071 Tuya sockeye salmon. An alternative method was based on combining inriver commercial and test fishery CPUE. Proxy commercial CPUE were used post week 32 . The proxy figures were based on the linear relationship between the commercial CPUE and the test fishery CPUE in 1986-04. All of the weekly data sets were significantly correlated. Based on this run reconstruction approach, the final escapement estimates are 27,492 non-Tahltan and 7,066 Tuya sockeye salmon. The non-Tahltan spawning escapement estimate is within the escapement goal range of 20,000 to 40,000 fish. Aerial survey counts of non-Tahltan sockeye salmon, however, indicated a record low run. The index count of 120 fish, observed on $09 / 10$, was $88 \%$ below the average of 973 fish. The low counts were unexpected in light of the near record test fishery CPUE of mainstem fish in August. Several index sites were flown again on $09 / 15$ but the survey did not yield a count that was measurably higher than the first survey. The possibility of the misidentification of mainstem fish in the test and
commercial catches (estimated by egg diameter measurements greater the 3.6 mm ) is being investigated. Eggs diameters collected at the Tahltan Lake weir indicated that the eggs of Tahltan fish were measurable larger this year than in the past five years. The average egg diameter at the Tahltan Lake in 2007 was 3.6 mm , while the 2002-2006 average egg diameter was 3.3 mm . An unusually large component of the sampled fish at the First Nation fishery located near Telegraph Creek, B.C had eggs greater than 3.6 mm . Genetic analysis from scale samples may be conducted to assess weekly proportion of mainstem sockeye salmon in fishery catches.

The existence of planted Tuya escapement continues to be a concern because of straying of this stock to other Stikine River tributaries. Furthermore, the injury to Tuya River sockeye salmon attempting to ascend the lower reaches of the Tuya River is evident based on reports from First Nations fishers and stock assessment personnel. (A study on the behavior of Tuya river sockeye salmon strays was conducted in August and September, 2004 and April and May 2005 and concluded that in the short term the straying of Tuya River sockeye salmon does not pose a genetic risk to natural mainstem Stikine River sockeye salmon; however, over the long term, given enough straying, an interaction of Tuya strays with natural sockeye salmon may occur.) To address problems associated with fish capture in the lower Tuya River, a newly designed fishway/trapping apparatus was constructed during the spring of 2006. Unfortunately the Tuya fishtrapping project was not prosecuted because of a major rock slide at the Tuya River fishing site that occurred sometime in June 2006. The rockslide rendered the fishing site, for which the fish trap was groomed for, unusable due to changes and river hydrology as well as the unsafe working conditions at the site. More rockslide activity occurred in May and June 2007.

A steering committee, consisting of Canadian and US engineers and others visited the site in August 2007 to assess the conditions and to consider and discuss other fish capture options. The steering committee decided to proceed with a blasting plan so designed to provide fish passage around the newly formed barrier. The project is scheduled to start in mid to late March 2008. A proposal, funded through the Northern Fund, requesting weir and trap design at a site located upstream from the blasting site will be tendered to engineering firms in the spring of 2008. The proposal will cover both design and cost of a trap as well as the routing and cost of a tote road to the fishing site.

## Chinook Salmon

The 2007 Chinook salmon escapement enumerated at the Little Tahltan weir was 562 large fish and 12 jack Chinook salmon (Appendix A.21). The escapement of large Chinook salmon in the Little Tahltan River was $8 \%$ of the average of 7,298 fish and below the MSY escapement goal for this stock of 3,300 large Chinook salmon. Because of extremely high water conditions the weir was installed approximately one week later than normal. The weir was inundated with flood waters for several days at the onset of the project. It was felt that few fish transited the weir undetected during this period. The annual aerial survey conducted by ADF\&G in early August supported this claim in that the proportion of aerial count to weir counts were not unusual in 2007. (Surveyors typically count $30-40 \%$ of the what was enumerated at the weir.)

A mark-recapture study was conducted again in 2007 concurrent with the SCMM to assess the inriver Chinook salmon abundance. Mark-capture estimates were calculated after week 25 (week ending June 23). The final estimate of system-wide spawning escapement, based on tag recoveries in the commercial fishery was 14,599 large Chinook salmon, $40 \%$ of the average of 36,624 large Chinook salmon and 2,841 fish below the escapement goal of 17,400 large Chinook salmon. The escapement to the Little Tahltan River represented $4 \%$ of the Stikine River escapement. The percentage is below the average Little Tahltan contribution of $20 \%$.

Stikine River Chinook salmon run timing to the Lower Stikine commercial fishing grounds was approximately one week later than normal. Fish arriving at the Little Tahltan weir were three weeks late. Very high water conditions may have been the cause of the delay and perhaps the paucity of fish entering the Little Tahltan River. Verrett Creek escapements counts were also weak as reported by the carcass pitch crew stationed at the creek from 02-12 August. A very weak run of Shakes Creek Chinook salmon was also reported by residents living at the creek mouth. Aerial surveys of the mainstem Tahltan River yield very low counts (These were conducted as part of Stikine Chinook salmon genetics baseline project. No samples were collected due to the poor showing of fish.)

## Coho Salmon

Aerial surveys of eight index sites were conducted on 10 November. The combined count of 1,557 coho salmon, under relatively good viewing conditions, was $40 \%$ of the average of 3,866 coho salmon.

No Stikine River coho salmon test fishery was conducted in 2007 due to budget issues. This test fishery has been operated a various levels of vigor since 1986 and provided managers with some level of confidence in assessing inseason run strength.

## Sockeye Salmon Run Reconstruction

The estimate of the terminal Stikine River sockeye salmon run size is approximately 196,785. Of this number, approximately 122,867 were of Tahltan Lake origin (wild \& planted), 36,227 were of Tuya origin (fry from Tahltan broodstock planted into Tuya Lake), and 37,690 were mainstem stocks (Table 3). These estimates are based on scale pattern analysis and otolith analysis in the U.S. Districts 106 and 108 catches; otolith analysis, egg-diameter stock-composition estimates for inriver catches from the Canadian commercial, aboriginal, ESSR, and test fishery catches; and escapement data. The 2007 total run was above average but below the preseason forecast of 233,500 fish.

## TAKU RIVER

Taku River salmon are harvested in the U.S. gillnet fishery in the Alaskan District 111, in northern Southeast Alaska seine and troll fisheries, and in the Juneau area sport fishery and inriver personal use fishery (Figure 2). Canadian fisheries for Taku River salmon include a commercial gillnet fishery located in the river near the Canada/U.S. border, an aboriginal fishery, and a sport fishery.

Figure 2. The Taku River and principal U.S. and Canadian fishing areas.

## Harvest Regulations

New fishing arrangements were in place in 1999 as a result of negotiations between Canada and the United States of Annex IV, Chapter 1 of the Pacific Salmon Treaty. As with the fishery regimes for the Stikine River, details of the February 2005 agreement including harvest sharing provisions as well as the fishery regimes adopted in 1999 are included in the Transboundary Annex (Annex IV) of the Pacific Salmon Treaty and can be found at: http://www.psc.org/pubs/treaty.pdf.

## U.S. Fisheries

The traditional District 111 commercial drift gillnet salmon fishery was open for a total of 64 days from June 17, through October 11, 2007 (Appendix C.1). The harvest totaled 1,223 large Chinook, 229 jack Chinook, 112,241 sockeye, 22,394 coho, 100,375 pink, and 590,169 chum salmon. Harvests of Chinook, sockeye, coho, and pink salmon and were below average, and the harvest of chum salmon was above average. Weekly commercial fishery harvests and stock composition estimates for these fisheries are provided in Appendices C.1-C. 3

Hatchery stocks contributed substantially to the numbers of both sockeye and chum salmon harvested and minor numbers to the harvest of other species. The 2007 season was the eighth year of substantial numbers of adult sockeye salmon returning to the Snettisham Hatchery inside Port Snettisham. These fish contributed substantially to the harvests primarily in Stephens Passage. The Speel Arm Special Harvest Area (SHA) inside Port Snettisham was not opened to common property fishing in 2007.

The total 2007 traditional drift gillnet large Chinook salmon harvest in District 111 was 1,223 fish and included 238 alaska hatchery fish or $19 \%$ of the harvest. Due to insufficient preseason and inseason estimates, there was no directed Chinook salmon fishery in District 111 this season.

The Taku River stock assessment program at Canyon Island and spawning ground recapture provided data to estimate the above-border large Chinook salmon run. The above-border run was 17,396 large Chinook salmon and the spawning escapement was 14,854 fish, below the lower bound of the current $30,000-55,000$ fish range.

The traditional District 111 sockeye salmon harvest was 112,241 fish, $73 \%$ of the average of 154,978 fish (Appendix C.1). Weekly sockeye salmon harvests were below average during all weeks with the exception of week 36. Weekly sockeye salmon CPUE was below average in all weeks except weeks 30 and 31 . Domestic hatchery sockeye salmon stocks began to contribute to the traditional fishery in week 28 and added substantial numbers to the harvests in weeks $30-33$. Fishermen targeting these runs of hatchery sockeye salmon and the Limestone Inlet hatchery chum salmon increased the amount and percentage of fishing effort that occurred in Stephens Passage. Of the total traditional District 111 sockeye salmon harvest, $32 \%$ occurred in Stephens Passage, greater than the average of $27 \%$. The harvest consisted of 60,879 wild Taku, 3,684 planted Tatsamenie, 11,353 wild Snettisham, and 31,213 domestic hatchery fish. The domestic hatchery fish
were predominately Port Snettisham hatchery sockeye salmon but also included a small number of thermally marked fish from a fry-planting program at Sweetheart Lake in Port Snettisham. The inseason estimate of stock composition of the harvest of wild sockeye salmon (based on historical averages) in the traditional district was 61,000 ( $57 \%$ ) wild Taku River fish, and 11,400 ( $11 \%$ ) wild Port Snettisham fish. Due to lower than anticipated runs of wild and enhanced Port Snettisham sockeye salmon, the Speel Arm SHA was not opened during the common property fishery in 2007.

The traditional District 111 chum salmon harvest of 590,169 fish was above the average of 282,027 fish (Appendix C.1). The summer chum salmon harvest of 581,843 fish comprised $99 \%$ of the season's chum salmon harvest. The summer chum salmon run is considered to last through mid-August (week 33) and was comprised mostly of domestic hatchery fish, with small numbers of wild fish contributing to the harvest. Chum salmon runs to DIPAC hatcheries in Gastineau Channel and to the DIPAC remote release site at Limestone Inlet contributed a major portion of the harvest but quantitative contribution estimates were not available. Approximately $66 \%$ of the total traditional District 111 chum salmon harvest was made in Taku Inlet, $34 \%$ in Stephens Passage, and $0.24 \%$ inside Port Snettisham. The harvest of 8,382 fall chum salmon, week 34 and later, was above the average of 3,582 fall chum salmon. Most of these chum salmon are assumed to be wild fish of Taku and Whiting Rivers origin.

The District 111 pink salmon harvest of 100,375 fish was below average. (Appendix C.1).

Coho salmon stocks harvested in District 111 include runs to the Taku River, Port Snettisham, Stephens Passage, and local Juneau area streams as well as Alaskan hatcheries. The traditional District 111 coho salmon harvest of 22,399 fish was below the average of 26,854 fish (Appendix C.1). Weekly coho salmon harvests were above average during weeks 26-29, and weeks 33-36. Coho salmon CPUE was above average during weeks 26-29, and week 35. CWT analyses indicate Alaskan hatchery coho salmon contributed 344 fish or $2 \%$ of the traditional District 111 harvest. Early season estimates of Taku River coho salmon abundance indicated an above average run size, but later estimates indicated a below average run size.

The 2007 preseason forecast of 38,720 large Taku Chinook salmon did not allow for a directed Chinook salmon fishery beginning May 1 in District 111. Subsequent inseason estimates did not support a directed Chinook salmon fishery. The 2007 District 111 drift gillnet fishery opened in June 17th in week 25.

Management actions to conduct the Taku River directed sockeye salmon drift gillnet fishery were limited to imposing restrictions in time and area. Because there is no bilaterally agreed forecast for Taku River sockeye salmon, early season management of the District 111 fishery is based on fishery CPUE and Canyon Island fish wheel catches. As the fishing season progresses sufficient data is acquired to estimate the inriver run size from the mark-recapture program at Canyon Island and to use that estimate in conjunction with migratory timing and historical fishery harvest data to forecast the entire

Taku sockeye salmon run. In the first opening, week 25 (June 17-June 23), two days of fishing time were allowed in both Taku Inlet (Subdistrict 111-32) and Stephens Passage (Subdistrict 111-31) to conserve the weaker than expected Chinook salmon run . The traditional District 111 sockeye salmon harvest in the first week was $34 \%$ of average.

In week 26 (June 24-June 30), District 11 was open for three days, then extended an additional day with above average CPUE in the gillnet fishery, strong fish wheel catches, and half the average effort. The sockeye salmon harvest in week 26 was $75 \%$ of average. In week 26, the first sockeye salmon inriver run projection estimate was 71,700 fish (on time run) or 190,400 (late run) announced (Table 4). Conversations with fishery managers in other parts of the State suggested a statewide trend of late and compressed sockeye salmon run timing this season.

Table 4. U.S. inseason forecasts of terminal run size, TAC, inriver run size, and the U.S. harvest of Taku River sockeye salmon for 2007.

| Stat | Inriver <br> Run | Terminal <br> Run $^{\text {a }}$ | Total <br> TAC | U.S. | Projected <br> Week |
| :--- | ---: | ---: | ---: | ---: | ---: |
| 26 | 70,694 | 110,931 | 35,931 | 29,463 | U.S. Catch |
| 27 | 45,205 | 45,205 | 0 | 0 | 40,237 |
| 28 | 85,662 | 136,385 | 61,385 | 48,381 | 0 |
| 29 | 60,699 | 110,858 | 35,858 | 28,420 | 50,723 |
| 30 | 62,922 | 124,571 | 49,571 | 40,154 | 50,159 |
| 31 | 78,342 | 136,755 | 61,755 | 49,118 | 61,650 |
| 32 | 103,372 | 164,678 | 89,678 | 72,444 | 58,414 |
| Postseason | 98,581 | 169,765 | 88,732 | 70,654 | 61,306 |

${ }^{a}$ Terminal run does not include any marine harvest of Taku River salmon that might occur outside of District 111.

With below average observed effort and good fishing opportunities in nearby areas preventing an influx of effort, fishing time in District 111 for week 27 (July 1-July 7) was set for four days. The traditional District 111 sockeye salmon harvest in week 27 was $59 \%$ of average.

In week 28 (July 8-July 14) District 111 was open four days with an inriver projection of 85,700 to 123,900 sockeye salmon and stable effort levels. The traditional District 111 sockeye salmon harvest for the week was $52 \%$ of average.

With low inriver indicators and poor sockeye salmon CPUE District 111 was open for three days during week 29 (July 15-July 21), and the traditional District 111 harvest was $61 \%$ of average.

During week 30 (July 22-July 28), District 111 was again open three days based on average fishery CPUE but poor inriver indicators. Record high water in the Taku River hampered stock assessment activities. The projected inriver estimate made in week 29 for week 30 , was 60,700 to 83,000 sockeye salmon. On the grounds surveys in week 30 indicated sockeye salmon CPUE rates near twice the average with $60 \%$ of the average effort. Although initial inriver projections were poor in week 30, confidence in the
accuracy of the estimate was low due to high river levels coupled with a Tulsequah flood event that occurred just prior to the opening. Fish wheel catches had been improving with declining river levels prior to the flood, and as water levels declined after the flood event fish wheel catches improved dramatically. District 111 was extended for one day in week 30. The traditional District 111 sockeye salmon harvest was $95 \%$ of average.

During week 31 (July 29-August 4) District 111 was open for three days as the cumulative US harvest through week 30 of 41,169 sockeye salmon exceeded the US TAC of 40,154 Taku origin fish. The inriver sockeye salmon projection was 73,700 to 88,000 fish and no extension was announced. Fish wheel catches improved through the week establishing a record daily catch of over 500 sockeye salmon. A bloom of diatoms in the waters of District 111 fouled nets and drove the fleet off the water on the final day of the fishery. The sockeye salmon harvest in week 31 was $75 \%$ of the average and the cumulative US harvest through week 31 of 47,000 sockeye salmon was less than the US TAC of 49,000 fish Otolith analysis indicated $21 \%$ of the sockeye salmon harvest in Taku Inlet and 70\% in Stephens Passage were Snettisham hatchery origin fish.

During week 32 (August 5-August 11), Taku Inlet was open for four days due to improving inriver indicators. Stephens Passage was held to three days with below average escapements to Port Snettisham systems.. The entrance to Port Snettisham (11134) was open for three days in week 32 to target returning Port Snettisham hatchery sockeye salmon. Inriver mark-recapture estimates indicated 74,000 sockeye salmon had past all fisheries and the PSC target of 75,000 fish sockeye salmon escapement had nearly been realized. The traditional District 111 drift gillnet sockeye salmon harvest of 20,400 fish was the best of the season, $76 \%$ of average.

During week 33 (August 12-August 18) Taku Inlet was open for four days with adequate sockeye salmon escapement to the Taku River. Stephens Passage and Port Snettisham were open for three days with developing concern over sockeye salmon escapements to Speel and Crescent Lakes. Section 11C (111-20) was open for three days with adequate pink salmon escapements to area streams. Effort levels in week 33 were the highest of the season with 105 boats making landings in expectation of the projected good run of Snettisham hatchery sockeye salmon. The harvest in District 111 was $40 \%$ of average, reflecting the weaker than anticipated run of Port Snettisham hatchery sockeye salmon. These fish contributed $29 \%$ of the harvest in Taku Inlet, $78 \%$ of the harvest in Stephens Passage and $88 \%$ of the harvest in Port Snettisham. The week 33 District 111 coho salmon harvest was $156 \%$ of average.

The fall drift gillnet season in District 111, when management focus switches from sockeye to coho salmon abundance lasted eight weeks, beginning on August 19, week 34, and lasting until October 11, week 41. The first ADFG inriver coho salmon estimate generated in week 32 indicated a strong run, and the inriver projection announced in week 33 of 53,000 fish was above the 38,000 PST minimum above border goal. In the first week of the fall season (week 34), fishing time was set at four days in Taku Inlet with the fourth day restricted to the area north of the Pete's Rock line to allow harvest of Taku River origin coho salmon and provide relief to wild Port Snettisham sockeye
salmon. Stephens Passage and Section 11C were held to three days in week 34, and the entrance to Port Snettisham was closed for the remainder of the season. The traditional District 111 sockeye salmon harvest for week 34 was $24 \%$ of the average (Appendix C.1) The week 34 traditional District 111 coho salmon harvest was above average. The traditional District 111 chum salmon harvest of 3,500 fish was twice the average. Section 11 C closed for the season at the end of the week 34 fishery, with little catch and effort during the two weeks of fishing.

With a good coho salmon projection Taku Inlet was open for four days in week 35 (August 26-September 1), with the last two days restricted north of the Pete's Rock line to protect any wild Port Snettisham sockeye salmon that may still be transiting the area. Stephens Passage was open for two days. The coho salmon harvest in week 35 was the highest of the season with 52 boats harvesting 6,600 coho salmon, $238 \%$ of average with coho salmon CPUE $116 \%$ of the average. The harvest of 1,500 chum salmon in week 35 was over twice the average.

For the remainder of the season, weeks 36-41, Taku Inlet was open for four days each week based on adequate Taku River coho salmon escapements and a continually diminishing fleet. Stephens Passage was open for a more conservative three days each week with respect to the little information on coho salmon escapements to local streams. The 4,400 coho salmon harvested by 50 boats in week 36 (September 2-September 8) was $111 \%$ of average with CPUE dropping to half of the average and the 2,600 chum salmon harvested was over four and a half times the average harvest for the week. In week 37, effort declined to 30 boats and 2,100 coho salmon were harvested $43 \%$ of the average with a CPUE $27 \%$ of average. The week 37 (September 9-September 15) chum salmon harvest of 660 fish was $117 \%$ of average. Effort dropped to 11 boats in week 38 (September 16-September 22) and 4 boats in week 39 (September 23-September 29), and coho salmon harvests diminished with CPUE $27 \%$ and $20 \%$ respectively of the average for these weeks. Chum salmon harvests and CPUE declined as well, the latter falling to $70 \%$ and then $36 \%$ of the average for these weeks. For the remaining two weeks of the fishery, harvest information is confidential with less than three boats fishing. The season was closed to further fishing on October 11 at the end of week 41.

Several other fisheries in the Juneau area harvested transboundary Taku River salmon stocks in 2007. Personal use permits were used to harvest an estimated 450 Taku River sockeye salmon. In 2007, an estimated 3,520 Chinook salmon were harvested by sport fisheries in the Juneau area. A number of stocks are known to contribute to the Juneau area sport fishery, including those from the Taku, Chilkat, and King Salmon rivers, and local hatchery stocks, but the major contributor of large, wild mature fish was believed to be the Taku River. Of the Chinook salmon harvested 1,416 were estimated to be of Taku River origin based on coded wire tag analysis and maturity data. The July Hawk Inlet shoreline commercial purse seine pink salmon fishery in Chatham Strait was not opened in 2007. A large number of stocks, including the Taku River, contribute to this pink salmon directed fishery. A purse seine test fishery was conducted each week in week 25 through week 29 between Hawk Inlet and Point Retreat, the results indicated below average abundance of pink salmon so no fishery was prosecuted.

## Canadian Fisheries

The Taku River commercial fishery harvest was 16,714 sockeye, 5,121 coho, and 874 large Chinook and 424 jack Chinook salmon (Appendix C.4). An additional 1,396 large Chinook were taken in a commercial assessment fishery which was prosecuted in place of a test fishery prior to June 17. The sockeye salmon catch was $63 \%$ of average. Fish originating from Taku fry plants contributed an estimated 1,602 fish to the catch, comprising $9 \%$ of the total sockeye salmon harvest. The catch of coho salmon was $14 \%$ above the average. The catch of large Chinook salmon was $31 \%$ of average (Appendix D.5). In 2005, as a result of the new Chinook salmon agreement which allows directed Chinook salmon fishing if abundance warrants, catch accounting for small salmon was revised from a commercial weight-based designation (previously referred to "jacks" which were typically fish under 2.5 kg or 5 kg , depending on where they were being marketed), to a length-based designation (small Chinook salmon i.e. less than 660 mm in length from the middle of the eye to fork of tail (MEF)). Hence, comparisons with catches from previous years should be noted accordingly. There were 77 days of fishing; this was 1.8 times the average; this could be explained in part by extremely high water levels which lowered catch rates substantially, making for longer openings. The seasonal fishing effort of 313 boat-days was $97 \%$ of average. These figures do not include the Chinook salmon assessment (test) fishery in 2007 or the directed Chinook salmon fishing which took place in 2005 and 2006. As in recent years, both set and drift gillnets were used with the majority of the catch taken in drift gillnets. The maximum allowable mesh size was 20.4 cm ( 8.0 inches) until June 17 at which point it was reduced to 15.0 cm ( 5.9 inches) in order to minimize incidental catch of Chinook salmon.

In addition to the commercial catches, 167 large Chinook, 16 jack Chinook, 159 sockeye, and 155 coho salmon were harvested in the aboriginal fishery in 2007. It is estimated that 15 of the sockeye salmon originated from the Tatsamenie fry planting program. The catches in the Taku aboriginal fishery have averaged 167 Chinook, 211 sockeye, and 343 coho salmon and two steelhead.

Recreational harvest figures are not available. It has been assumed that on average approximately 300 large Chinook salmon are harvested annually. Applying aerial survey data (in 2007, surveys with normal or above average viewing conditions were $35 \%$ of average) to this figure gives an assumed harvest of 105 large Chinook salmon. The catches of other species are believed to have been negligible.

As noted, a commercial assessment (test) fishery to capture Chinook salmon for stock assessment purposes took place from April 29 through June 17 (weeks 18-24) and landed 874 large Chinook and 424 small Chinook salmon. A coho salmon test fishery took place from September 2 through October 5 (weeks 36-40) and landed 2,676 coho and 375 sockeye salmon; it is estimated that 20 of these sockeye salmon originated from the Tatsamenie Lake fry planting program.

The bilateral preseason Chinook salmon forecast, based on sibling relationships, indicated a terminal run of 38,720 fish, $33 \%$ of the average run of approximately 57,600
fish (Canadian estimate). This fell short of the number required for directed fishing, specifically 42,400 fish (the escapement goal point estimate, plus test fishery allocation as well as Canadian and U.S. base level catches). Normally, a test fishery would be prosecuted to provide the data for inseason estimates of abundance. However, due to a recent Canadian court case referred to as the Larocque decision, Canada was unable to issue a license for test fishing in 2007. Instead, the commercial fishery was opened at an assessment level and managed to the weekly guidelines developed for the test fishery (Table 5).

Table 5. Canadian inseason forecasts of terminal run size, total terminal allowable catch (TTAC), and spawning escapement of Taku Chinook salmon, 2007.

| Stat Week | Terminal Run | Canada $B L C C^{a}$ | Test Fishery Quota | Weekly Guideline | Actual Catch |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 17 |  |  |  | 125 | 38 |
| 18 |  |  |  | 175 | 240 |
| 19 |  |  |  | 225 | 224 |
| 20 |  |  |  | 250 | 265 |
| 21 | 16,404 |  |  | 250 | 256 |
| 22 | 16,428 |  |  | 225 | 229 |
| 23 | 18,889 |  |  | 150 | 143 |

| Total | 27,321 |  | 1,400 |  |  |

${ }^{\mathrm{a}}$ Canada base level catch.
The commercial assessment fishery was monitored intensively; initially, openings were kept short until a feel for CPUE was garnered. Where necessary, when the weekly target had been achieved, openings were terminated through revocation of variation order or on a voluntary basis.

The first opening was for a four-hour period beginning at 8:00 a.m. on Monday, April 30, week 18. After catch information from this opening was evaluated, an additional 52-hour period was permitted starting Tuesday noon. This was extended to Saturday noon, given low effort and low catches. Two licenses fished and the weekly catch was 38 fish, 87 fish below the target of 125 .

Week 19 commenced noon Sunday May 6 for an initial 24 -hour period. This was followed by three one-day extensions for a weekly catch of 240 fish, exceeding the weekly target of 175 fish, and addressing some of the short fall from the first week to leave a cumulative balance of 22 fish. As in the first week, there were two licenses fishing.

Week 20 opened on Monday May 13 at 8:00 a.m. for an initial four-hour period. This was followed by a three-hour period on Tuesday and a six hour period on Wednesday, starting at 2:00 p.m. and noon respectively. A final ten-hour opening beginning noon on

Thursday was revoked at 6:00 p.m.; the final catch for the week was within one fish of the target of 225 fish. A balance of 22 fish from the previous week remained; postponing this catch to the following week was of value from a stock assessment perspective as very few tags had been applied at Canyon Island to date. There were five licenses fishing this week.

The week 21 opening, starting May 20, was delayed until Monday noon in part due to the dearth of tagged fisher released from Canyon Island; it was anticipated that fishwheels would be operational by the end of the weekend. The Monday opening was eight hours in duration. The fishery was opened again on Tuesday from noon to 6:00 p.m. A final tenhour opening on Wednesday was revoked at $6: 30$ p.m. The weekly target of 250 fish had been achieved and most of the shortfall eliminated.

The first Canada/U.S. joint inseason run size projection was made after the week 21 opening. Mark-recapture data was marginal, however, with only eight tags recovered. It was estimated that 5,034 fish had passed the international border, and 547 fish had been harvested in the U.S sport fishery through week 19. This was expanded using historical run timing at Canyon Island to give a terminal run size projection of 16,404 fish, well below both the preseason forecast of 38,720 fish, and the trigger for directed commercial fishing in Canada, 42,400 fish.

The commercial fishery continued in assessment mode; openings for week 22 , starting May 27, were Sunday from noon to 8:00 p.m. and noon Tuesday to Wednesday noon initially but extended to 8:00 p.m.. The catch of 256 Chinook salmon brought the cumulative catch to within two fish of target. Three licenses fished. There was little change to the terminal run size projection after week 22 . Openings for week 23, starting June 3, were Sunday noon to 8:00 p.m., Monday noon to 10:00 p.m., Tuesday noon to Wednesday noon, Thursday noon to Friday noon and finally a three day opening ending at noon Monday (week 24). Water levels rose quickly from well above average levels on Sunday to record levels on Thursday rendering fishing conditions poor. The weekly catch of 229 Chinook salmon, within four fish of the harvest target, was achieved by 7:00 pm on Saturday and there was a voluntary cessation of fishing until noon the following day. Up to six licenses were fishing on any given day this week. The terminal run projection made in week 23 was 18,889 fish; only a slight increase over the first two projections and still well below the forecast and fishery trigger.

River conditions on Sunday June 10 (week 24) were favorable and catches rates were higher than seen in much of the previous week. A total of six licenses fished. A late afternoon hail indicated that fishers were likely to reach the weekly target of 150 that day. Fishers were permitted to continue fishing until 10:00 pm since fishing conditions were deteriorating due to rapidly rising water; also, spreading the catch over an additional calendar day would have been of limited value from a stock assessment perspective since only three tags had been applied at Canyon Island in the previous nine days. The final catch for the week was 143 Chinook salmon, bring the cumulative total for the assessment fishery to 1,395 fish, five fish below the target of 1,400 fish. The terminal run
projection made after the week 24 opening was almost identical to the one made in week 23 ( 18,400 fish versus 18,889 ).

Week 24 was the final week of the assessment fishery. Four more terminal run projections of terminal run size were made after this time using bycatch during the directed sockeye salmon fishery. Terminal run projections made in weeks 25 (starting June 17), 27 (starting June 24) and 28 (starting July 1) were 20,108, 26,669 and 24,337 fish respectively. The final joint inseason estimate of terminal run size was made in week 28 (starting July 8); and amounted to 27,321 fish, short of the preseason forecast of 38,720 fish. This was based on an inriver run estimate of 24,291 , expanded by the average timing of fish passing Canyon Island through July 7 (97\%). The final harvest totals in the commercial assessment, aboriginal, commercial bycatch and recreational harvest, were estimated to have been $1,395,874,167$, and eight fish respectively totaling 2,445 fish. Subtracting this from the inriver run projection of 24,932 , the escapement is estimated to have been 22,488 fish, substantially short of the target of 36,000 fish. Postseason analysis of the mark-recapture data, including spawning ground tag recovery results, is in progress.

The cumulative commercial fishery Chinook salmon CPUE was 259 fish per boat day (FBD), approximately $23 \%$ higher than the cumulative CPUE observed in 2005. CPUE ranged from a low of 13 FBD in week 18 to a high of 56 FBD in week 25.

Week 25 marked the start of the sockeye salmon season. As in past years, for the sockeye and coho salmon fisheries, guideline harvests were developed each week to guide management decisions so that: a) the catch was consistent with conservation and Treaty goals; and b) management was responsive to changes in projections of abundance, i.e. abundance-based. The guidelines were based on current inseason forecasts of the Canadian TAC (based on mark-recapture estimates) apportioned by historical run timing.

The Canadian preseason forecast for the total run of wild sockeye salmon was 211,700 fish. This was a drainage-wide stock recruitment-based forecast; a sibling-based forecast was not produced in 2007 as SPA to determine the contribution of Taku fish to U.S. harvests in 2006 was still in progress. The stock-recruitment-based forecast was $13 \%$ of the average run size of 245,000 sockeye salmon (Canadian estimate). These figures assume U.S. harvest of 5\% in marine approach waters (outside District 111); the terminal run forecast was therefore approximately 201,100 fish.

The directed sockeye salmon commercial fishery commenced in week 25 (June 17-June 23), as noted above, for a scheduled opening of two days. Mesh size was restricted to sockeye salmon gear only, i.e. it was reduced from 20.4 cm ( 8.0 inches) to 15 cm ( 5.9 inches); this restriction was in place for the remainder of the season. Based on the preseason forecast, the weekly guideline was 1,443 sockeye salmon (Table 6). However, based in part on fishwheel catches, which were below average, it appeared that the run was delayed and Chinook salmon considerations were foremost. Water levels were extremely high, within $2 \%$ of the record. CPUE for day 1 was only 20 FBD (133 fish) as
compared to an average of 70 FBD. The fishery was closed as scheduled. The catches for the week were 316 sockeye and 284 Chinook salmon.

Table 6. Canadian inseason forecasts of total run size, total allowable catch (TAC), and spawning escapement of Taku sockeye salmon, 2007.

| Stat. <br> Week | Total Run | TAC | Projected <br> Escapement | Canadian <br> TAC | Inseason <br> guideline | Actual <br> Catch |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| 25 | 211,733 | 136,733 | 75,000 | 24,612 | 1,443 | 316 |
| 26 | 211,733 | 136,733 | 75,000 | 24,612 | 3,465 | 1,320 |
| 27 | 127,502 | 52,502 | 48,634 | 9,450 | 2,241 | 2,141 |
| 28 | 122,347 | 47,347 | 78,275 | 8,523 | 2,883 | 3,044 |
| 29 | 158,706 | 83,706 | 55,103 | 15,067 | 7,075 | 3,324 |
| 30 | 134,291 | 59,291 | 55,167 | 10,672 | 6,497 | 4,403 |
| 31 | 118,779 | 43,779 | 88,065 | 7,880 | 5,795 | 8,412 |
| 32 | 163,838 | 88,838 | 89,180 | 15,991 | 13,247 | 12,033 |
| 33 | 171,157 | 96,157 | 91,312 | 17,308 | 15,794 | 14,513 |
| 34 | 182,133 | 107,133 | 91,312 | 19,284 | 18,368 | 15,500 |
| 35 | 176,132 | 101,132 | 87,301 | 18,204 | 17,789 | 15,787 |

Week 26 (June 24-June 30) was opened for three days. The cumulative guideline harvest through this week based on the preseason forecast was 3,465 fish, with a balance of 3,149 fish. The CPUE was 31 FBD on day 1 and improved to 39 FBD on day 2, the water levels were dropping and fishwheels were showing consistent catches. Consequently, the fishery was extended by one day. The sockeye and Chinook salmon catches for the week were 1,004 and 345 fish respectively.

The week 27 fishery (July 1-July 7) opened for three days. The cumulative guideline harvest through this week based on the preseason forecast was 5,837 sockeye salmon, of which there was a balance of 3,696 fish. At the close of day 2 , CPUE had doubled from day 1, fishwheel counts were above average and water levels were dropping; consequently a one-day extension was permitted. An inseason estimate made mid-week indicated a run of 130,000 fish, with a guideline harvest of 2,348 fish (Table 6). However, there were indications that the run was late and applying a one-week late timing increased the projection to 219,000 fish, with a cumulative guideline harvest of 4,007 fish. The weekly catch was 821 fish bringing the cumulative catch to 2,141 sockeye salmon. The weekly Chinook salmon catch was 175 fish.

Week 28 (July 8-July 14) was opened for two days. An inriver abundance estimate produced after day 1 was slightly lower than week 27 's and consequently the run projection dropped to a range of 122,347 to 206,137 fish (guideline harvest range: 2,883 to 7,976 fish). CPUE on day 1 was about half of weekly average ( 43 versus 78 FBD) despite relatively favorable water levels (only slightly above average and dropping) and the fishery was not extended. Water levels increased dramatically over the remainder of the week. The balance in the guideline harvest at closing ranged from -161 to 3,107 fish. Weekly catches were 903 sockeye and 51 Chinook salmon.

Week 29 (July 15-July 21) opened for three days and was extended two days due in part to a Tulsequah River flood which limited catches. Fishwheel catches were below average for the period. The total sockeye salmon catch for the week was 280 fish, for a cumulative catch of 3,324 fish. The balance in the cumulative harvest ranged from 3,751 to 6,679 fish. The average CPUE for the week was 11 FBD compared to an average of 98 FBD.

Week 30 (July 22-July 28) opened for three days. Both on-time and one week late run projections after day 3 were below the preseason forecast and ranged from 134,000 to 186,000 fish; the concomitant guideline harvest range was 6,497 to 9,415 fish, with substantial balances. Consequently the fishery was extended to five days in one-day increments. Water levels dropped throughout the week to finish slightly above average. However CPUE was well below average ( 31 versus 102 FBD). The catch for the week was 1,079 sockeye salmon, leaving guideline balances of 2,094 and 5,012 fish assuming average and one-week late timing respectively.

Week 31 (July 29-August 4) was opened for three days. This was the first week for which special consideration for the Tatsamenie sockeye salmon stock was identified in the management plan. Fortunately, indications were that the run was building as fishery CPUE had increased substantially from the previous week. The U.S. manager was consulted after day 1 and with the highest CPUE of the season it was agreed that the run did appear to be late and that an extension was justified. Consequently the fishery was extended to six days. A run assessment assuming one-week late timing made after day 2 projected a run of 197,000 sockeye salmon and a guideline harvest balance of 4,308 fish. The final catch for the week was 4,009 fish. Fishery CPUE increased to slightly below average in week 31 ( 84 vs. 98 FBD), with the highest CPUE on day 6.

Week 32 (August 5-August 11) was again opened on three days due to Tatsamenie sockeye salmon considerations. The day 1 CPUE of 195 FBD was the season's highest. Canyon Island fishwheel counts were approximately four times average. A run projection assuming average timing produced after day 3 was approximately 191,000 fish leaving a guideline harvest balance of 5,878 fish. After consultations with the U.S. manager, the fishery was opened at Saturday noon for one additional day. The weekly catch of sockeye salmon was 3,621 fish.

Week 33 (August 12-August 18) was initially opened for two days. The opening was extended to five days based on an anticipated reduction in fishing effort (ten licenses to six licenses) and a guideline harvest balance ranging from 1,231 to 3,150 fish. The sockeye salmon catch for the week was 2,480 fish.

Week 34 (August 19-August 25) marked the beginning of coho salmon season. The preseason outlook was for an average run based on catches in the 2006 coded-wire tagging program. Assuming that U.S. exploitation rates on coho salmon would be similar to the 2002-2006 average, it was estimated that border escapement would be close to 100,000 fish, which meant that the Canadian allowable catch was 10,000 fish. Early indications were that the coho salmon run was strong with good catches in the fishery and
consistently higher than average catches in the fishwheels. This information coupled with the shortfall in the sockeye salmon guideline harvest was used to open the fishery for four days. Fishery performance was strong with double the average coho salmon catches for the week. The total catches were 990 coho and 987 sockeye salmon.

The six-day opening for week 35 (August 26-September 1) based on an inseason run projection for coho salmon of approximately 216,000 fish. Weekly landings were 850 coho and 287 sockeye salmon.

A final inseason mark-recapture estimate for the inriver sockeye salmon run, produced after week 34, indicated an above border run of 98,500 sockeye salmon. A projection of 101,155 fish is based on average timing ( $98 \%$ ). Subtracting the inriver harvest of 16,900 fish ( 16,366 commercial, 159 aboriginal and 375 test) indicated that spawning escapement was in the vicinity of 84,255 sockeye salmon, just above the escapement goal range of 71,000 to 80,000 fish. The postseason analysis of above border run size and spawning escapement data is in progress. The cumulative commercial fishery sockeye salmon CPUE for the season was $560 \mathrm{FBD}, 44 \%$ of the average. CPUE was below average throughout the season except for weeks 31-33. Peak CPUE was observed in week 32; on average CPUE peaks in week 31.

The commercial fishery was then opened from week 36 (starting September 2) to late in week 40 (October 5). However, week 36 proved to be the last week of substantial commercial activity, with 1,062 coho and 578 sockeye salmon landed; landings after this totaled six fish.

In order to continue coho salmon run assessment, a test fishery operated from September 2 through October 5, weeks 36-40. This fishery landed 375 sockeye and 2,676 coho salmon.

A final inseason coho salmon mark-recapture estimate produced at the end of week 39 indicated that 47,334 fish had reached the border. Based on average run timing, this projected to 57,486 fish. Accordingly, as per PST provisions, the Canadian allowable catch after week 33 was 5,000 coho salmon. Based on inseason data, the actual treaty catch of coho salmon in the commercial fishery was 3,016 fish; this includes an aboriginal harvest of 155 fish but not the 2,676 fish caught in the test fishery for run assessment purposes. Subtracting the total inriver harvest of 7,952 fish translates to a final inseason spawning escapement estimate of 49,534 fish, approximately $42 \%$ above the upper end of the escapement goal range (27,500-35,000 fish). Postseason analysis of fishery and mark-recapture data is in progress. The cumulative commercial coho salmon CPUE through week 41 was 230 FBD, $74 \%$ of the average. The truncated nature of the coho salmon fishery in recent years makes the use of CPUE for inriver run timing assessments of limited value.

## Escapement

## Sockeye Salmon

Spawning escapement of sockeye salmon into the Canadian portion of the Taku River drainage is estimated from the joint Canada/U.S. mark-recapture program. Counting weirs operated by DFO at Little Trapper and Tatsamenie Lakes and by the TRTFN at Kuthai and King Salmon Lakes provide information on the distribution and abundance of discrete spawning stocks within the watershed.

The sockeye salmon mark-recapture program has been operated annually since 1984 to estimate the above-border run size; spawning escapement is then estimated by subtracting the inriver catch. Final inseason estimates of above border run size and spawning escapement in 2007 are 105,012 and 87,764 sockeye salmon, respectively. The spawning escapement was $80 \%$ of the average (Appendix D.9), and above the upper end of the interim escapement goal range of 71,000 to 80,000 sockeye salmon.

The sockeye salmon count through the Kuthai Lake weir was 204 fish, the lowest count on record ( 1,015 fish observed last year). The 2007 count was $4 \%$ of the average and $3 \%$ of the primary brood year escapement of 7,799 fish (Appendix D.10). However, it is speculated that high water levels in the Silver Salmon River may have prevented fish from reaching the lake. The sex composition was estimated at $72 \%$ female.

The Little Trapper Lake weir count of 7,153 was $49 \%$ of average and $48 \%$ of the estimated primary brood year escapement of 11,484 fish (Appendix D.10). The sex composition was estimated at $67 \%$ female. Run timing was about twelve days later than average, with the mid-point occurring on August 20. Approximately 813 fish were held for artificial spawning; details are presented in the enhancement section of this report.

The Tatsamenie Lake weir count of 11,187 was $33 \%$ above average and approximately double the primary brood year count of 5,495 . The sex composition was estimated to be $61 \%$ female. The mid-point or migratory timing occurred on August 31, about five days earlier than average. However the first fish arrived at the weir a week later than average. Approximately 2,803 fish were held for artificial spawning; details are presented in the enhancement section of this report. Final data based on a sample of otoliths taken from these fish suggest that approximately $27 \%$ of the fish originated from the fry planting program.

A weir was operated at King Salmon Lake for the fifth consecutive season; however only five fish (three females and two males) were observed. This occurred on July 31 and August 1. A cursory aerial scout of the river did not identify any blockages. Several hundred sockeye salmon were observed in the lake however, in early September - it appears that these fish moved into the lake after the weir was removed. Escapement counts for 20032006 have averaged 2,789 fish (the 2002 count of 2,970 is based on a boat survey as only a partial weir count was obtained that year). Run timing has been variable to date; in 2006, the mid-point was on July 28.

## Chinook Salmon

Spawning escapement of Chinook salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tag application effort took place from late April through early October with the last tag applied in July. Tag recovery effort consisted of the commercial assessment (test) fishery from April 29 through June 17, weeks 18-24, the sockeye and coho salmon commercial fisheries, weeks 25-37, and spawning ground sampling in August and September on the Nakina, Tatsatua, Kowatua, Nahlin, Dudidontu and Hackett rivers. Fishery tag recovery data was used to generate a bilateral postseason border passage estimate of 20,058 large Chinook salmon; subtracting harvest of 2,542 indicates that an estimated 17,516 large Chinook salmon escaped to spawning areas. This spawning escapement was approximately half of the target of 36,000 fish (the mid-point of the escapement goal range of 30,000 to 55,000 fish), and below the lower end of the range. In comparison the average escapement is 47,710 fish (Appendix D.11).

Aerial surveys of large Chinook salmon to the six escapement index areas annually surveyed by ADF\&G were as follows: Nakina, not available due to poor conditions; Kowatua, 262 fish; Tatsamenie, 390 fish; Dudidontu, 4 fish; and Nahlin, 277 fish; Tseta Creek was not flown (Appendix D.12). Survey conditions were poor due to flooding on the Nakina, Nahlin and Dudidontu Rivers. The total of 933 large Chinook salmon observed was $14 \%$ of average.

A carcass weir was operated on the Tatsatua river in order to obtain tag and age-lengthsex data. A total of 136 large Chinook salmon were encountered, $30 \%$ of the fish encountered in 2006. (The 2006 count in the Tatsatua was compromised somewhat by high water levels.) No carcass weir was installed on the Nakina River in 2007 due to high water.

## Coho Salmon

Spawning escapement of coho salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Coho salmon were tagged at Canyon Island from week 27 through week 40 . Recovery efforts in the commercial and test fishery occurred from week 27 (concurrent with sockeye salmon recovery efforts) through week 40. The postseason border and spawning escapement estimates are 82,319 fish and 74,367 fish respectively (Appendix D.13). The spawning escapement was $47 \%$ of average and above the upper end of the interim escapement goal range ( 27,500 to 35,000 fish).

## Pink Salmon

There is no program to estimate the escapement of Taku River pink salmon; however, the Canyon Island fish wheels provide an index of annual variation in border escapement. A total of 12,405 pink salmon was captured the fish wheels in 2007, $90 \%$ of the odd-year average (Appendix D.15).

## Chum Salmon

As with pink salmon, the Canyon Island fish wheels are used to determine annual variations in border escapement. A total of 482 chum salmon was captured in the wheels in $2007,55 \%$ above average (Appendix D.15). The Taku River fall chum run has been depressed since 1988. It is unlikely that the spawning escapement goal of 50,000 to 80,000 fish has been achieved in recent years.

## Steelhead Trout

There was no program in place to estimate the system-wide steelhead trout escapement. An escapement goal has not been set for this species. A total of 57 steelhead trout were caught and released at Canyon Island in 2007; this count was 57\% of average (Appendix D.15).

## Sockeye Salmon Run Reconstruction

An estimated 60,879 wild Taku sockeye salmon were caught in the U.S. District 111 commercial gillnet fishery. This final estimate was made by applying the weekly average proportion of Taku sockeye salmon to the weekly catch of wild fish (the estimated hatchery produced sockeye salmon were first subtracted from the weekly catches). An additional 534 sockeye salmon were estimated to have been taken in the U.S. inriver personal use fishery. The estimated total U.S. harvest of wild Taku sockeye salmon is 61,413 fish (Table 7).

In the Canadian commercial fishery, the final catch estimate of wild Taku sockeye salmon is 14,696 fish. An estimated 144 wild sockeye salmon were taken in the Canadian aboriginal fishery. Therefore, the estimated Canadian treaty harvest of wild Taku sockeye salmon is 15,131 fish (Table 7). An additional estimated 339 wild sockeye salmon were taken in test fisheries.

The contribution of Taku sockeye salmon from the fry planting program was estimated based on expansion of otolith-marked sockeye salmon recovered in the sampled catch. Estimates are 3,684 in the District 111 fishery, 55 in the inriver personal use fishery, 1,602 in the Canadian commercial fishery, and 15 in the aboriginal fishery (Table 7). The inriver coho salmon test fishery caught an estimated 36 sockeye salmon originating from the fry planting program.

The final estimate of the above-border run size of sockeye salmon, based on the joint Canada/U.S. mark-recapture program, is 104,886 fish. Deducting the Canadian inriver catch of 17,123 fish (in commercial, test and aboriginal fisheries) from the above-border run estimate results in an escapement estimate of 87,764 sockeye salmon. The total run of Taku sockeye salmon is estimated at 170,015 fish. Based on the mid-point of the escapement goal range of 75,000 fish, the U.S. TAC was 75,809 fish with an actual harvest of 65,151 and the Canadian TAC was 19,229 with an actual harvest of 16,748 fish. The harvsts do not include test fishery catches.

Table 7. Taku sockeye salmon run reconstruction, 2007. Estimates do not include spawning escapements below the U.S./Canada border.

${ }^{\text {a }}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

## ALSEK RIVER

Alsek River salmon stocks contribute to the U.S. commercial gillnet fisheries located in Dry Bay, at the mouth of the Alsek River (Figure 3). Unknown quantities of Alsek River origin fish are also taken in the U.S. commercial gillnet and troll fisheries in the Yakutat area. No commercial fishery exists in the Canadian portions of the Alsek River drainage,
although aboriginal and recreational fisheries occur in the Tatshenshini River and some of its headwater tributaries (Figure 3).

## Harvest Regulations \& Management Objectives

Although catch sharing of Alsek River salmon stocks between Canada and the U.S. has not yet been specified, Annex IV does call for the development and implementation of cooperative abundance-based management plans and programs for Alsek River Chinook, sockeye and coho salmon. Interim escapement goal ranges for Alsek River sockeye and coho salmon were initially set by the TTC at 33,000 to 58,000 sockeye, and 5,400 to 25,000 coho salmon. The principle escapement-monitoring tool for Chinook, sockeye, and coho salmon stocks on the Alsek River is the Klukshu weir, operated by DFO and the Champagne-Aishihik First Nation (CAFN). The weir has been in operation since 1976. To make the management objectives of Chinook and sockeye salmon better defined in terms of Klukshu stocks, revised goals, expressed in terms of Klukshu stocks only, were established in 1999 and adopted again in 2004. Mark-recapture programs to estimate the total inriver abundance and the fraction of the escapement contributed by the Klukshu stocks were in operation since 1997 for Chinook salmon and since 2000 for sockeye salmon. These however were discontinued in 2005.

The initiative to establish a specific Klukshu Chinook salmon spawning goal began in 1991 when the TTC set an interim spawning objective of 4,700 Klukshu Chinook salmon. This goal was based more on manager's intuition than on science. From 1995 through 1997, the TTC reviewed this escapement level and concluded that goal of 4,700 Chinook salmon was not supported by the data. A new goal range of 1,100 to 2,300 fish was proposed based on joint analyses of stock-recruitment data. The Parties conducted independent internal reviews of these analyses. Although there was not unanimous support
for the proposal, there was agreement on establishing a minimum goal consistent with the lower end of the proposed range. As a result, Canadian and U.S. managers agreed to a minimum spawning escapement goal of 1,100 Chinook salmon for the Klukshu system for 2000 and this was used again in the 2007 season.

The stock-recruitment analysis of Klukshu sockeye salmon data was completed in 2000 and has undergone internal peer review. The new escapement goal range for Klukshu River sockeye salmon is 7,500 to 15,000 spawners per year.

## Preseason Forecasts

The overall sockeye salmon run to the Klukshu River in 2007 was expected to be near average in strength. Principal contributing brood years to the 2007 run were expected to be 2002 (Klukshu escapement of 23,587 fish) and 2003 (Klukshu escapement of 32,120 fish); the 1997-2006 average Klukshu escapement was 13,856 fish. The estimated production of Klukshu sockeye salmon for 2007 was 20,000 fish. Based on historical stock-recruitment analysis, the range of Klukshu escapements that appear most likely to produce maximum sustained yields is 7,500 to 15,000 sockeye salmon.

Figure 3. The Alsek River and principal U.S. and Canadian fishing areas.

The 2007 overall Alsek River sockeye salmon run was expected to be approximately 75,000 fish. This estimate was based on: a predicted run of 20,000 Klukshu sockeye salmon derived from the average of the historical Klukshu stock-recruitment data and an assumed Klukshu contribution of $27 \%$ (based on the 2001-2003 sockeye salmon radio tagging study). A run size of this magnitude is near the average run size estimate of approximately 66,500 fish (based on the Klukshu weir count expanded by $1 / 0.27$ to account for other inriver escapement and an assumed U.S. harvest rate of $20 \%$ ).

The contributing Klukshu early sockeye salmon run counts in 2002 and 2003 were 11,904 and 3,084, respectively (Appendix C.7). The principal brood year (2002) was well above the optimum level of 2,500 sockeye salmon spawners as determined through separate stock-recruitment analyses by DFO of the early run. Due to the over escapement in 2002, the early run was expected to be 3,000 which is below the average.

The Klukshu Chinook salmon escapements in 2001 and 2002 were 1,738 and 2,134 fish, respectively. The 2001 and 2002 escapements were near average and near the upper end of the optimum escapement range of 1,100 to 2,300 Chinook salmon estimated from current stock-recruitment analysis. As a result, the final outlook was for an above average run. The 2007 overall Alsek River Chinook salmon run was expected to be approximately 16,000 fish. This estimate was based on: a predicted run of 2,800 Klukshu Chinook salmon derived from the historical Klukshu stock-recruitment data; and an assumed Klukshu contribution to the total run of approximately $17 \%$.

The coho salmon escapements observed at the Klukshu River in 2003 (3,689 coho salmon) and 2004 ( 750 coho salmon) suggests the run in 2007 would be average (Appendix C.7). The 1997-2006 average weir count was approximately 2,600 coho salmon.

## U.S. Fisheries

Although harvest sharing arrangements of Alsek salmon stocks between Canada and the U.S. have not been specified, Annex IV of the Pacific Salmon Treaty does call for a cooperative attempt to rebuild depressed Chinook and early-run sockeye salmon stocks. The Alsek River commercial fishery opened on the first Sunday in June, week 23. The initial opening remained at 1 day. The fishery was opened for one day in week 24 and was extended 1 day due to because of high CPUE. The opening for week 25 was one day and the fishery was extended an additional two days due to high CPUE. The fishery was opened for one day in weeks 26-29 and was extended an additional one day in each week due to high CPUE. The opening for week 30 was held to one day. Effort in the Alsek River became minimal from week 31 through the remainder of the fishery. The fishery was open for three days in week 31 and two days in week 32 . The fishery targeted coho salmon after mid-August and fishing times remained at three days per week for the entire coho salmon season. Although the Alsek River remained open through the third week in October, no effort was recorded after September 30.

The 2007 Dry Bay commercial set-gillnet fishery harvested 400 Chinook, 19,791 sockeye, and 134 coho salmon (Table 8). No pink or chum salmon were harvested. A test fishery conducted on the Alsek River for Chinook salmon in 2007 captured another 347 Chinook and 367 sockeye salmon, for a total harvest of 747 Chinook and 20,162 sockeye salmon. The Chinook salmon harvest was below average, while the sockeye salmon harvest was above average. The coho salmon harvest was below average. Very little effort was recorded during the coho salmon season due to market conditions and the coho salmon harvest was the second lowest in the last 10 years. The number of fishing days
was 38. The total effort expended in the fishery was 311 boat-days, which was above average.

Table 4. Final Catch and Klukshu index escapement data for Alsek River sockeye, Chinook, and coho salmon for 2007.

|  | Sockeye | Chinook | Coho |
| :--- | ---: | ---: | ---: |
| Escapement Index $^{\text {a }}$ |  |  |  |
| Klukshu Weir Count | 8,956 | 677 | 300 |
| Klukshu Escapement | 8,479 | 676 | 299 |
|  |  |  |  |
| Harvest $^{\text {b }}$ |  |  |  |
| U.S. Commercial | 19,791 | 400 | 134 |
| U.S. Subsistence | 72 | 28 | 0 |
| U.S. Test | 367 | 347 | 0 |
| Canadian Sport | 10 | 40 | 0 |
| Canadian Aboriginal | 0 | 0 | 0 |
| Total | 20,240 | 815 | 134 |

${ }^{\text {a }}$ Klukshu River salmon stocks represent an assumed large and variable portion of the total Alsek River salmon escapement.
${ }^{\mathrm{b}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

## Canadian Fisheries

Due to the elimination of the harvest monitor position in 2005, catches from the food fishery are largely unknown. The only harvest information for 2007 was the fish taken from Klukshu River weir which was 1 Chinook, 477 sockeye, and 1 coho salmon. The average catches were 123 Chinook, 1,223 sockeye, and 16 coho salmon.
Final catch estimates for the Tatshenshini recreational fishery were below average for Chinook salmon, with an estimated 40 fish retained, and sockeye salmon, with an estimated harvest of 10 fish, and no catches recorded for coho salmon. These represented $30 \%$ of average for Chinook, $22 \%$ of the average for sockeye, and $0 \%$ for coho salmon. Retention of sockeye salmon in the Tatshenshini River was permitted starting on August 15th as per regulation.

Management of salmon in the Yukon is a shared responsibility between DFO and the Yukon Salmon Committee (YSC). The YSC was established in 1995 pursuant to the Comprehensive Land Claim Umbrella Final Agreement between the Government of Canada, the Council for Yukon Indians and the Government of the Yukon. The Committee is a public board consisting of ten members, $70 \%$ of which are appointed by Yukon First Nations. Two CAFN members sit on the YSC. Although the Committee currently operates by consensus, the voting structure of the Committee is organized so that, should a vote be necessary, $50 \%$ of the votes reside with appointees of Yukon First Nations.

The 2007 Alsek-Tatshenshini management plan, adopted by CAFN, YSC, and DFO, was based on the objectives described in the Harvest Regulations \& Management Objectives section above. For Chinook and early run sockeye salmon management, the status of the Klukshu weir counts was to be reviewed on or about July 18 to ensure weir and spawning escapement targets were on track. The status of the late run sockeye salmon would be reviewed the first week of September. Adjustments to inseason fishing regimes in the recreational and aboriginal fisheries would be made if deemed necessary. Other key elements of the plan are described below.

The center of aboriginal fishing activity in the Alsek River drainage occurs at the CAFN village of Klukshu, on the Haines road, about 60 km south of Haines Junction. Salmon are harvested by means of gaff, small gillnets, sport rods, and traditional fish traps as the fish migrate up the Klukshu River and into Klukshu Lake. The fishing plan for the aboriginal fishery in the Klukshu River for the period prior to August 15 allowed fishing by means of fish traps for two days per week. After August 15, it was planned that the traps would be fished three days per week. Conservation thresholds that might invoke restrictions in the Aboriginal fishery were projected Klukshu weir counts of $<1,100$ Chinook and <1,500 early sockeye salmon. Food fisheries also exist on Village Creek and in the headwaters of the Tatshenshini River and tributaries thereof (Goat Creek, Stanley Creek, Parton River, and the Blanchard River). The plan did not restrict the fishery other than to reserve Goat Creek, Stanley Creek, and the Parton River for elders only.

The majority of the recreational fishing effort on this drainage occurs on the Tatshenshini River, at and just downstream of the mouth of the Klukshu River in the vicinity of the abandoned settlement of Dalton Post. The management plan prohibited the retention of sockeye salmon in the recreational fishery prior to August 15 unless the weir count projection for the early run was $>4,500$ sockeye salmon. The Chinook salmon daily catch limit was one fish and the possession limit was two Chinook salmon. For other salmon species, the daily catch and possession limits were two, and four fish, respectively. However, the aggregate limit for all salmon combined was two salmon per day, four fish in possession. Starting in 2003, recreational salmon fishing was permitted in the Tatshenshini River seven days a week; this fishery had previously been open from 6:00 am Saturday to 12:00 noon Tuesday each week. Headwater areas upstream of the British Columbia/Yukon border were to be closed in late July to protect spawning Chinook salmon. Conservation thresholds that were expected to invoke additional restrictions in the recreational fishery were projected Klukshu weir counts of $<1,500$ Chinook and < 10,600 sockeye salmon (early and late runs combined).

A mandatory Yukon Salmon Conservation Catch Card (YSCCC), introduced by the YSC in 1999, was required by all recreational salmon fishers in 2007. The purpose of the YSCCC is to improve harvest estimates and to serve as a statistical base to ascertain the importance of salmon to the Yukon recreational fishery. Anglers are required to report their catch via mail by the late fall. Information requested includes the number, sex, size, date and location of salmon caught and released.

Since 2001, CAFN has imposed a fishing area closure from the Klukshu River Bridge crossing up to the new weir location to allow for better staging opportunities for salmon in the vicinity of the Klukshu/Tatshenshini confluence.

## Escapement

Total drainage abundance programs are being implemented as part of the development of abundance-based management regimes and to accurately assess whether the escapement goals for Alsek River Chinook and sockeye salmon stocks are appropriate and if so, are being achieved. At this time, there are no programs in place to estimate the drainage-wide coho salmon escapement. A large and variable proportion of the escapement of each species is enumerated at the weir on the Klukshu River. Current escapement monitoring programs including the Klukshu weir, Village Creek electronic counter, and aerial surveys allow annual comparisons of escapement indices. The most reliable long-term comparative escapement index for Alsek River drainage salmon stocks is the Klukshu River weir count. Escapements for 2007 are shown in Table 8.

## Sockeye Salmon

The final weir count and escapement estimates of Klukshu River sockeye salmon were 8,956 and 8,479 fish respectively in 2007 (Table 8, Appendices C. 3 and C.7). The count of 2,725 early run fish (count through August 15) was $96 \%$ of average while the count of 6,231 late run fish was $57 \%$ of average. The total escapement $(8,479)$ was below average, and was near the lower end of the recommended escapement goal range of 7,500 to 15,000 fish. The sockeye salmon escapement estimate at the Village Creek counter of 10,254 fish in 2007 was 5.5 times the average and the largest count on record.

## Chinook Salmon

The most reliable comparative Chinook salmon escapement index for the Alsek River drainage is the Klukshu River weir count. The final Chinook salmon weir and escapement counts in 2007 were 677 and 676 fish, respectively (Table 8), and were $38 \%$ and $39 \%$ of average. The 2007 escapement was below the revised interim escapement goal range of 1,100 to 2,300 Klukshu Chinook salmon.

## Coho Salmon

The Klukshu weir count and escapement of 300 and 299 fish, respectively, is approximately $12 \%$ of their respective averages (Table 8). The weir is removed prior to the completion of the coho salmon run and dos not include fish that migrate after midOctober.

## ENHANCEMENT ACTIVITIES

## Egg Collection

In 2007, sockeye salmon eggs were collected at Tahltan Lake on the Stikine River for the twentieth year, and in the Tatsamenie Lake system on the Taku River, for the eighteenth year of this program.

## Tahltan Lake

The egg collection was contracted to Arc Environmental Ltd. for the twelfth consecutive year. The egg-take goal at Tahltan Lake is 6.0 million eggs; due to low escapement 3.8 million eggs were collected. A total of 2,839 fish were collected and held for broodstock. Fish were captured with a beach seine at the major spawning site as has been done in most years. There were 11 egg collections from September 7 to 27 . Eggs were collected from 1,380 females and a like number of males. Eggs collected on six days were delayed in shipment to the hatchery due to weather; of the delayed shipments, one was delayed 48 hours and the remainder only 24 hours.

## Tatsamenie Lake

B. Mercer and Associates Ltd was contracted to collect eggs. Tatsamenie Lake broodstock was captured for the thirteenth year at an adult enumeration weir located at the outlet of Tatsamenie Lake. A total of 1,500 females and 1,300 males were held prior to the first egg take on September 17. An estimated 4,100,000 eggs were collected from 994 females and milt was collected from 850 males during 8 egg collections. Mortality of held fish included $76(4 \%)$ females and $139(10 \%)$ males; the remaining 435 females and 309 males not used for gamete collection were released. The 1,500 females held for broodstock represented $25 \%$ of the estimated escapement of females in to the lake.

## Trapper Lake

Eggs were again collected at Trapper Lake for assessment work related to proposed barrier removal. This project was operated with Northern Fund monies but will be reported in TBR reports. A total 813 fish were held prior to the first egg take on September 8. An estimated 830,000 eggs were collected from 336 females and milt was collected from 295 males during 3 egg collections; these eggs were transported to Snettisham Hatchery. There were also 122,000 eggs planted in Tunjony Creek on September 13th for assessment purposes. Evaluation of egg plants will take place in the spring using fyke nets and hydraulic sampling.

Incubation, Thermal Marking, and Fry Plants (2003 Brood Year)
The egg incubation and thermal-marking program at Snettisham Hatchery went smoothly in year 2006/2007. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and

Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Incubation of 2006 brood eggs took place at Snettisham Hatchery and the resultant fry were transported to the appropriate systems from May 31 to June 20, 2006. There were no IHN virus losses of sockeye salmon fry from transboundary lakes.

## Tahltan Lake

A total of 2.47 million fry from the 2006 Tahltan sockeye salmon egg take was planted back into Tahltan Lake in 2007. Survival from green-egg to outplanted fry was $84 \%$. Fry outplanting took place from May 31 to June 4.

## Tuya Lake

There were 1.2 million fry planted in Tuya Lake from June 19 to June 20. These fish were from eggs collected at Tahltan Lake in the fall of 2006. Survival from green-egg to outplanted fry was $85 \%$.

## Tatsamenie Lake

A total of 3.7 million fry from the 2006 egg-take was released into Tatsamenie Lake in 2007. There were three treatment groups: one group was released at the North end and one at the South end of the lake, and a third group mid lake; outplanting took place from May 31 to June 13. Survival from green-egg to outplanted-fry was $77 \%$.

The strategy behind releasing at the different locations is to put some fry in an area with little natural production. The south end of the lake traditionally has few fry along the shore. Past studies have indicated a protracted shore residence for hatchery and wild fry. However results so far indicate lower survival from the fry release at the South end.

## Outplant Evaluation Surveys

## Acoustic, Trawl, Beach seine and Limnological Sampling

Standard limnological surveys were conducted at Tatsamenie, Tahltan, Trapper and Tuya Lakes. Hydroacoustic surveys with a newly purchased Bio-Sonics unit were conducted at Trapper Lake.

## Thermal Mark Laboratories

## ADF \&G Thermal Mark Laboratory

During the 2007 season the ADFG thermal mark lab received otoliths from 17,900 sockeye salmon collected by ADFG and DFO staff as part of the U.S./Canada fry-
planting evaluation program. These collections came from commercial and test fisheries in U.S. waters and in Canadian fisheries on the Taku and Stikine Rivers over a 12 -week period. In addition, several escapement samples were examined. Combined, the laboratory processed 17,200 of the otoliths received ( $96 \%$ ) and provided estimates on hatchery contributions for almost 100 distinct sampling collections. Of these totals, 4,400 otoliths were identified and classified as belonging to one of 35 marked groups. Estimates of the percentage of hatchery fish contributed to commercial fishery catches were provided to ADFG and DFO fishery managers 24 to 48 hours after samples arrived at the lab.

Adult sockeye salmon otoliths were processed inseason by the ADFG otolith lab to estimate the weekly contribution of planted sockeye salmon to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Final contributions of planted sockeye salmon stocks to catches were as follows: 59,491 planted Stikine River fish to District 106 and 108 and inriver subsistence, and 3,739 planted Taku River fish to District 111 (includes inriver personal use fishery). Final estimates of contributions to Canadian fisheries included 31,019 planted Stikine River fish to Stikine River fisheries and 1,617 planted Taku River fish to the Taku River fisheries.

## Canadian Thermal Mark Laboratory

Sub-samples of juvenile and adult otolith samples collected at the study lakes during the 2007 season are being analyzed at the DFO thermal mark lab in Whitehorse. In most cases $50 \%$ of collected samples were processed for final analysis. Results were used for estimates of enhanced numbers in escapements and smolt projects.

## APPENDICES

Appendix A. 1. Weekly salmon catch in the Alaskan District 106 commercial drift gillnet fisheries, 2007.
Effort may be less than the sum of effort from 106-41\&42 and 106-30 because some boats fished in more than one subdistrict.
Chinook are large fish only; MEF length $\geq 660$.

| Week | Start <br> Date | Catch |  |  |  |  | Effort |  |  |

${ }^{\text {a }}$ No broodstock collected in 2007.

Appendix B. 1. Salmon catch and effort in the Alaskan District 106 commercial drift gillnet fisheries, 1960-2007.
Effort may be less than the sum of effort from 106-41/42 and 106-30 since some boats fished in more than one subdistrict.
Chinook are large fish only; MEF length $\geq 660$.

${ }^{\text {a }}$ Generated from a mark-recapture study (ADF\&G fisheries data series)
${ }^{\mathrm{b}}$ As reported in the mark-recapture reports
${ }^{c}$ From jointly accepted US and Canadian catch estimates
${ }^{\mathrm{d}}$ Terminal run does not included chinook catches taken beyond the Stikine River or District 108.

Appendix B. 29. Index counts of Stikine coho salmon escapements, 1984-2007.
Missing data due to poor survey conditions.

${ }^{\text {a }}$ The averages for 1983-1985 are averages of weekly run timing estimates as well as stock composition estimates and are not simple averages of total estimates for the season.
${ }^{\mathrm{b}}$ Escapement includes fish later captured for broodstock and biological samples

Appendix C. 1. Weekly salmon catch and effort in the Alaskan District 111 and Subdistrict 111-32 (Taku Inlet), commercial drift gillnet fishery, 2007.
Chinook are large fish only; MEF length $\geq 660$.

${ }^{a}$ Chum Salmon are not included because of the difficulty of making an accurate estimate, the majority of the summer chum catch was of hatchery origin.

Appendix C. 2. Estimate of the proportion of natural and planted sockeye salmon stock groups harvested in the Alaskan District 111 commercial drift gillnet fishery by week, 2007.
Stock composition estimates are historical (1997-2006) averages, except for planted which are based on marked fish expansions. Does not inlcude Port Snettisham harvests.

| Spawners ${ }^{\text {a }}$ |  | 8,384 |  |

${ }^{\text {a }}$ Broodstock included 850 males and 994 females which were spawned successfully,
76 females and 139 males that did not survive holding, and 435 females and 309 males which were held and released unspawned. Twenty-three of these females were in moribund communication and would not have spawned; the spawning success of the other released fish is unknown.

-Continued-

Appendix D.1. Page 2 of 2.
Days open are for the entire district and include openings to harvest spawner chinook salmon, 1960-1975.
Chinook are large fish only; MEF length $\geq 660$.

Appendix D. 4. Salmon catch in the U.S. subsistence and personal use fisheries in the Taku River, 19672007.

The subsistence fishery was open 1967 to 1976 and 1985 and the personal use fishery was open 1989-2007.
The harvests are miminum estimates because not all permits are filled out and returned.
Chinook are large fish only; MEF length $\geq 660$.

${ }^{\text {a }}$ Incomplete harvest data.
${ }^{\mathrm{b}}$ In addition to these fish, 180 adult female chinook, one adult male chinook and four steelhead were captured and released live.
${ }^{\mathrm{c}}$ In addition to these fish 439 adult female chinook were captured and released live.
${ }^{\mathrm{d}}$ In addition to these fish, 871 adult female chinook, 2,976 coho, 82 sockeye, 159 chum and 116 steelhead were captured and released live.
${ }^{\mathrm{e}}$ In addition to these fish, 1,132 adult female chinook, 3,767 coho, 161 sockeye, 7 pink, 11 chum and 89 steelhead were captured and released live.
${ }^{\mathrm{f}}$ In addition to these fish, 4,031 coho, 197 sockeye, 7 pink, 222 chum and 175 steelhead were captured and released live.

Appendix D. 9. Taku River sockeye salmon run size, 1984-2007.

| Run estimate does not include spawning escapements below the U.S./Canada border. The early season sockeye expansion is based on the proportion of fish wheel sockeye catch that occurs before the fishery opens. |  |  |  |  |  |  |  |  |  |  |

${ }^{\text {a }}$ Mark-recapture estimates for Crescent 91, 92 Speel 95
${ }^{\mathrm{b}}$ Weir count plus spawning ground survey. Trapper 83, 85, 87
${ }^{c}$ Weir counts are incomplete. Kuthai 92, Nahlin 88, 92
${ }^{\text {d }}$ Counts may be low due to uncounted fish passage past weir. Crescent 88-90, Speel 90, Kuthai 93
${ }^{\mathrm{e}}$ In 1995 the weir was moved upstream to Tatsamenie Lake, the count of 8,000 is an expansion (based on past experiance) of the 5,780 fish counted there.
${ }^{\mathrm{f}}$ The estimated return of 10,381 through the Tatsamenie Lake weir in 1996 is thought to represent approximately $80 \%$ of the sockeye run past the old weir location at Little Tatsamenie Lake. This results in a potential run of 12,976 sockeye salmon.
${ }^{\mathrm{g}}$ The estimated return of 8,363 through the Tatsamenie Lake weir in 1997 is thought to represent approximately $80 \%$ of the sockeye run past the old weir location at L . Tatsamenie Lake resulting in a potential run of 10,454 sockeye.
${ }^{\text {h }}$ The estimated count of 5,997 fish through Tatsamenie Lake weir in 1998 does not include an estimated 1,499 fish spawning in the outlet stream i.e. total estimate 7,496.
${ }^{i}$ Minimum estimates of run size
${ }^{\mathrm{j}}$ In 2002 the Trapper weir count was expanded by $69 \%$ migratory timing to account for fish passage during high water and the Kuthai weir count had 102 fish removed for an aboriginal food fishery.

Appendix D. 11. Taku River Chinook salmon run size, 1989-2007.
Run estimate does not include spawning escapements below the U.S./Canada border.
Chinook are large fish only; MEF length $\geq 660$.

${ }^{\text {a }}$ Counts include jack chinook salmon.
${ }^{\mathrm{b}}$ Weir was removed prior to the end of the coho run.
${ }^{c}$ The chinook and sockeye escapements into Klukshu Lake are calculated from the weir count minus fish harvested above the weir site minus broodstock taken. The remainder of the food fishery harvest occurred below the weir, at Village Creek, and Blanchard and Takhanne Rivers.
${ }^{\mathrm{d}}$ Includes sockeye counts up to and including August 15.

Appendix E. 8. Alsek River sockeye salmon escapement 2000 to 2005.
The 2000-2004 estimates are based on mark-recapture studies. The 2005 estimate was based on GSI analysis and the expansion of the Klukshu River weir count.

[^29]
[^0]:    ${ }^{a}$ All Tahltan includes wild and thermally marked fish.

[^1]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.

[^2]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.

[^3]:    ${ }^{\text {a }}$ All steelhead were released
    ${ }^{\mathrm{b}}$ Based on studies conducted on survival of net-caught released Skeena River steelhead

[^4]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.
    ${ }^{\mathrm{b}}$ Catch and effort data used to generate cpue by stock group excluded the catch and effort above Porcupine.
    ${ }^{c}$ because the commercial fishing activity concluded before the run terminated, egg diameters from the test fishery and the rate of change in the egg diameters by week was applied to the prior weeks relative abundance of the stocks and
    a proxy cpue was based on a regression of District 108 cpue of Stikine fish vs inriver cpue with intercept forced to zero.
    ${ }^{d}$ because the commercial fishing activity concluded before the run terminated, egg diameters from the test fishery and a proxy cpue was used based on the historical relationship between the cpue observed in test fisheries against
    the catch per unit effort observed in a commerical fishery: (wk 33, r=0.67 df=18;wk 34, r=0.42, df=18; wk 35, r=0.23, df 16; wk 36, r=0.64,df=14) week 36 and $37 \mathrm{~m} / \mathrm{s}$ and Tahltan contributions are estimated.

[^5]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.
    ${ }^{\mathrm{b}}$ Used the proportion observed in stat wk 27 as a proxy for stat weeks 24-26

[^6]:    ${ }^{\text {a }}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

[^7]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.

[^8]:    ${ }^{\text {a }}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

[^9]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.
    ${ }^{\mathrm{b}}$ There was no data available to determine the ratio of Tahltan to mainstem Stikine stocks;
    1:1 ratio was assumed.

[^10]:    ${ }^{\text {a }}$ All Tahltan includes thermally marked fish.

[^11]:    ${ }^{\text {a }}$ There was no commercial fishery in 1984.

[^12]:    ${ }^{\text {a }}$ Catches in 1979 were included in the lower river commercial catches.
    ${ }^{\mathrm{b}}$ There was no commercial fishery in 1984.

[^13]:    ${ }^{\text {a }}$ There was no commercial fishery in 1984.
    ${ }^{\text {b }}$ Chinook averages only since 1983 when large fish and jacks were recorded separately.

[^14]:    ${ }^{a}$ Average proportions were from averages of weekly estimates.

[^15]:    ${ }^{\text {a }}$ Average proportions were from averages of weekly stock composition and migratory timing (from drift test fishery) estimates.

[^16]:    ${ }^{\text {a }}$ Survey conditions were exceptionally poor; therefore, the counts probably did reflect relative abundance.
    ${ }^{\mathrm{b}}$ Verrett Slough inundated with turbid Iskut water in 2002-2004.

[^17]:    ${ }^{\text {a }}$ Veiwing conditions at the Craig River site were poor in 2004.
    ${ }^{\mathrm{b}}$ West Katete and Katete not survey due to inclement weather

[^18]:    ${ }^{\text {a }}$ There was no test fishing during statistical weeks 22-35 inclusive.

[^19]:    ${ }^{\text {a }}$ Broodstock removals included 336 females and 295 males which were spawned successfully, 24 females and 3 males which did not survive holding, and 74 females and 81 males which were released unspawned after being held; it is not known if any of these released fish spawned successfully

[^20]:    ${ }^{\text {a }}$ S. Chum and F. Chum refer to Summer and Fall runs of these fish, fish harvested prior to week 34 are considered summer chum, and fish harvested in week 34 and beyond are considered fall chum.

[^21]:    ${ }^{\text {a }}$ The Trapper and Mainstem groups were combined in the 1989 analysis and were 45,573 fish.
    ${ }^{\mathrm{b}}$ Averages for individual stocks do not include 1989.

[^22]:    ${ }^{\text {a }}$ The Trapper and Mainstem groups were combined in the 1989 analysis with 13,792 fish or .744 proportion.
    ${ }^{\mathrm{b}}$ Averages do not include 1989.
    ${ }^{\text {c }}$ total planted include an otolith based estimate of 119 thermally marked Stikine fish.

[^23]:    ${ }^{\mathrm{a}}$ In years when sample size data is available (1999-present in the commercial and test fisheries, and 2003-2004 in the Aboriginal fishery) it was used to determine the number of large fish in the Canadian harvest. In years when sample data is not available, the average \% large in the commercial fishery from 1999-2004 (75\%) was applied to all catches except the recreational catch, which is assumed to be $100 \%$ large and comprise 300 fish annually.
    ${ }^{\mathrm{b}}$ U.S. catch includes D111 commercial gillnet and Juneau area sport fishery harvests; the estimate of large fish for the commercial fishery includes age-1.3 and older fish; all sport harvests are assumed to be large fish.

[^24]:    ${ }^{\text {a }}$ Weir count combined with spawning ground count. Tatsamenie 88-90, Yehring 86-87, Nahlin 92.
    ${ }^{\mathrm{b}}$ Incomplete weir count. Tatsamenie 85-87, 93, 95, 96; and Nahlin 92
    ${ }^{c}$ Count is an average of surveys by different observers. Flannigan 86, 87, 88, 90,91 ;sockeye 86, 87, 88, 90, 91; Fish 86, 88, 90, 91; Yehring 87, 88, 91, 92
    ${ }^{\mathrm{d}}$ Includes mark-recapture estimate. Yehring 89, 90
    ${ }^{\mathrm{e}}$ Poor survey conditions. Nahlin 91.
    ${ }^{\mathrm{f}}$ Foot survey. Yehring 92, Sockeye 92
    ${ }^{\mathrm{g}}$ Surveys conducted before peak abundance on spawning grounds Flannigan 93, 94

[^25]:    ${ }^{\text {a }}$ Jack chinook included in the counts.

[^26]:    ${ }^{\text {a }}$ Surveys not made every year at each tributary.
    ${ }^{\mathrm{b}}$ Includes several streams from Lo-Fog to Goat Creek.
    ${ }^{\mathrm{c}}$ Incomplete count due to machine malfunction.
    ${ }^{\mathrm{d}}$ No counts due to malfunction of the counter.

[^27]:    ${ }^{\mathrm{a}}$ Late survey date which missed the peak of spawning.

[^28]:    ${ }^{\text {a }}$ All eggs collected in 2000 and 2001 were for backplant into Tahltan Lake.

[^29]:    Eggs not transported but placed in inlake incubator; $2000=244,000,2001=865,000,2002196,000,2003=190,000$.
    ${ }^{\mathrm{b}}$ Survival rates are for hatchery eggs and hatchery fry plants and do not inlcude the lake incubators.
    ${ }^{c}$ All died to IHNV
