## EXECUTIVE SUMMARY

Estimates of catches and escapements of Pacific salmon returning to the transboundary Stikine, Taku, and Alsek Rivers for 2000 are presented and compared with historical patterns. Average, unless stated differently, refers to the 1990-1999 average. Relevant information pertaining to the management of appropriate U.S. and Canadian fisheries is presented and the use of inseason management models is discussed. Results from transboundary river sockeye salmon Oncorhynchus nerka enhancement projects are also reviewed.

## Stikine

The 2000 Stikine sockeye salmon run was estimated at 78,500 fish, of which 55,200 fish were harvested in various fisheries including test fisheries. An estimated 19,900 Stikine fish escaped to spawn, including 5,800 fish that migrated to the Tuya block that were not harvested. The catch and the run were below the average and the lowest since 1990. Spawning escapements were also below goals. The estimated U.S. commercial catch of Stikine sockeye salmon in Districts 106 and 108 was 21,700 fish and the Canadian inriver commercial, aboriginal, and ESSR fishery catches were $21,400,6,100$, and 1,300 fish, respectively. A U.S. test fishery in District 108 harvested 3,600 Stikine sockeye salmon and the Canadian inriver test fishery catch included 2,400 sockeye salmon. The postseason estimate of 78,500 sockeye salmon was below the preseason forecast of 138,000 fish. The Stikine Management Model over forecasted the run throughout the season. Weekly inseason model forecasts ranged from 95,000 to 183,000 sockeye salmon and the final inseason estimates were 54,000 (U.S.) and 47,000 (Canada) fish. Based on the inseason model estimates, both Parties harvested below their $50 \%$ target of the TAC. However, the final postseason run size estimate decreased to no allowable catch therefore both countries exceeded their $50 \%$ portion of the TAC: Canada harvested 14,762 (mainstem and Tahltan) and the U.S. harvested 9,983 (mainstem and Tahltan).

The broodstock collection and otolith sampling removed 1,700 and 400 sockeye salmon, respectively from the escapement to Tahltan Lake leaving a spawning escapement of 4,000 fish; below the spawning escapement goal of 20,000 fish. The estimated spawning escapement of 10,100 mainstem Stikine sockeye salmon was also below the objective of 20,000 to 40,000 fish for this stock group.

The Chinook salmon O. tshawytscha catch in Canadian commercial and aboriginal fisheries in the Stikine River was 3,100 large fish and 600 jacks; both above the average. An additional 700 large and 20 jack Chinook salmon were taken in the Canadian inriver test fishery. The U.S. marine catch of Chinook salmon (all stocks) in the District 106 and 108 mixed stock gillnet fisheries was 2,900 fish and was above average; the contribution of Stikine Chinook stocks is unknown. The U.S. District 108 test fishery harvested 20 Chinook salmon. The Chinook salmon spawning escapement of 6,600 large adults through the Little Tahltan River weir in 2000 was above above average and above the revised joint U.S./Canada escapement goal range 2,700 to 5,300 fish. The total Stikine River Chinook salmon escapement as estimated from a mark recapture study was 27,500 fish and was above average (1996-1999).

As with Chinook salmon, the U.S. marine harvest of Stikine coho salmon $O$. kisutch was unknown since there is no stock identification program for this species. Mixed stock coho salmon catches in Districts 106 and 108 were 96,200 and 5,700 fish, respectively, and both were below average. Alaskan hatchery fish comprised $50 \%$ ( 51,000 fish) of the coho salmon harvest from the two districts. The Canadian inriver coho salmon catch of 300 fish was below average. Test fishery coho salmon catch per unit effort (CPUE) indicated the inriver coho salmon run was $20 \%$ lower than the inriver sockeye salmon run. This suggests
the total coho salmon escapement was well below the interim escapement goal range of 30,000 to 50,000 fish. Aerial surveys of coho salmon spawning index sites also indicated a below average escapement, as did the total coho salmon run size of 25,500 fish (range: 13,700 to 55,800 ) as generated from a pilot, markrecapture study.

## Taku

The postseason estimate of the 2000 Taku sockeye salmon run was 236,400 fish, including an estimated catch of 161,100 fish and an above-border spawning escapement of 75,300 sockeye salmon. The run size was average, the total catch was above average, and the escapement was within the escapement goal range of 71,000 to 80,000 fish. An estimated 131,700 Taku sockeye salmon was harvested in the District 111 commercial fishery and was above average. An estimated 900 sockeye salmon was harvested in the U.S. inriver personal use fishery. Canadian inriver commercial and aboriginal fishery catches included 28,000 and 150 sockeye salmon, respectively. The commercial catch was average, whereas the aboriginal catch was below average. Since the escapement goal was expressed as a range, the resulting total allowable catch was also expressed as a range. In 2000, Canada harvested an estimated $17-18 \%$ and the U.S. harvested $80-85 \%$ of the total allowable catch.

The catch of large Chinook salmon in the Canadian commercial fishery in the Taku River was 1,600 fish, and was average; the harvest of 90 jack Chinook salmon was below average. The Canadian aboriginal fishery in the Taku River harvested 50 large Chinook salmon. The Chinook salmon catch in the District 111 mixed stock gillnet fishery was 1,100 fish and was below average. An estimate $40 \%$ of the catch was Alaska hatchery origin. The escapement of 6,000 Chinook salmon counted in Taku River index areas was below average but within the recently revised index escapement goal range of 5,800 to 10,500 fish.

The estimated above border run of Taku coho salmon in 2000 was 70,100 fish which was below average. The Canadian inriver commercial catch included 4,400 coho salmon which was below average. After upriver Canadian catches are subtracted from the inriver run, the above-border-spawning escapement was estimated at 64,700 coho salmon, which exceeds the minimum escapement goal of 38,000 fish. The U.S. harvest of 7,500 coho salmon in the District 111 mixed stock fishery which below average. Alaskan hatcheries contributed an estimated $7 \%$ of the District 111 harvest, or 500 fish.

The harvest of 54,700 pink salmon O. gorbuscha in District 111 was below average. Pink salmon were not retained in the Canadian commercial inriver fishery in 2000. The escapement of pink salmon to the Taku River was likely below average as evidenced by the fish wheel, catch and release of 6,500 pink salmon which was below average.

The catch of chum salmon $O$. keta in the District 111 fishery was 668,600 fish, composed of 665,600 summer run fish (prior to mid-August) and 3,000 fall run fish. The catch of summer chum salmon, primarily Alaskan hatchery stocks, was 2.9 times average and was the highest on record. The catch of fall chum salmon, composed of wild Taku River and Port Snettisham stocks, was below average. As with pink salmon, there was non-retention of chum salmon in the Canadian inriver fishery and the reported catch was 0 fish in 2000. Although spawning escapement was not known the Canyon Island fish wheel catch of 400 chum salmon was average.

#### Abstract

Alsek The Alsek sockeye salmon harvest of 9,500 fish in the U.S. commercial fishery was below average and was the fourth lowest on record. The Canadian inriver catch of 700 fish was below average and was also the fourth lowest on record. There were no fish retained in the sport fishery. The low catches were the result restrictions and closures in the commercial, sport, and aboriginal fisheries due to conservation

concerns. The Klukshu River weir count of 5,600 sockeye salmon was below average and the second lowest on record.

The Chinook salmon run to the Alsek River seemed average to below average. The U.S. Dry Bay catch of 700 Chinook salmon was above average. The combined Canadian sport and aboriginal fishery catch of 100 Chinook salmon was below average. The 1,400 Chinook salmon counted through the Klukshu River weir was below average. Of the total count, 1,300 Chinook salmon were estimated to have spawned, thus achieving the escapement goal range of 1,100 to 2,300 Chinook salmon, established by the TTC for 2000 . Aerial survey index counts of other spawning systems were below average.

Current stock assessment programs prevent an accurate comparison of Alsek coho salmon runs with historical runs. The U.S. Dry Bay catch of 5,100 coho salmon was average, while the combined Canadian inriver aboriginal and sport fishery catch of 50 fish was below of average. The low catches were due to closures in the fisheries due to sockeye salmon conservation concerns. The operation of the Klukshu weir does not provide a complete enumeration of coho salmon into this system since it was removed before the run was over, however, it does provide a suitable annual index. The count of 4,800 coho salmon was twice the average.

## Enhancement

Eggs and milt were collected from the year 2000 sockeye salmon escapements at Tahltan and Tatsamenie Lakes. For the fourth year in a row the 6.0 million egg-take goal was not achieved at Tahltan Lake due to low escapement. A total of 2.4 million eggs was collected at Tahltan Lake. At Tatsamenie Lake, the 3.0 million egg collection goal was achieved; however this goal was lower than the 5.0 million-egg target specified in the treaty. The committee had set a lower goal as they seek to improve the low survivals of fry planted in the lake.

Outplants of 1999 brood-year sockeye salmon fry in May and June 2000 included 2.2 million fry into Tahltan Lake, 0.9 million fry of Tahltan Lake origin into Tuya Lake, and 0.4 million fry into Tatsamenie Lake. Green-egg to planted-fry survivals were $80 \%, 82 \%$, and $76 \%$ for these outplants, respectively. Survival to emergence was generally at, or above, expected levels and there were no losses to Infectious Hematopoietic Necrosis (IHN). Losses from IHN have occurred in the past at Snettisham Hatchery and are expected in sockeye salmon culture.

Outmigrant smolt sampling was conducted at Tahltan and Tatsamenie Lakes in 2000. Total emigration from Tahltan Lake was estimated at 619,300 smolts with $43 \%$ ( 266,000 smolt) from past fry plants. Sampling at Tuya Lake was conducted to estimate age and size composition of the outmigrants but outmigration magnitude was not estimated. Sample size was limited due to logistics and timing. The Tatsamenie Lake mark-recapture program estimated that 191,400 smolts out-migrated from that system with planted fish contributing about $20 \%$ ( 39,000 smolts).

The egg incubation and thermal-marking program was continued at Snettisham Hatchery in 2000. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Adult sockeye salmon otoliths were processed inseason by the ADF\&G otolith lab to estimate the weekly contribution of fish from U.S./Canada TBR fry planting programs to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Contribution estimates of planted fish to Alaskan catches were 12,500 Stikine sockeye salmon to District 106 and 108 ( $13 \%$ of catch) and 1,600 Taku sockeye salmon to District 111 ( $1 \%$ of catch). Final estimates of contributions to

Canadian fisheries included 13,600 sockeye salmon (49\% of catch) to Stikine fisheries and 400 sockeye salmon to the Taku fisheries ( $2 \%$ of catch).

## INTRODUCTION

This report presents estimates of the 2000 catch and escapement data for Pacific salmon runs to the transboundary Stikine, Taku, and Alsek Rivers and discusses management actions taken during the season. Catch and effort data are presented by management week (U.S. statistical week) for each river for both U.S. and Canadian fisheries. Spawning escapement data for most species are reported from weir counts or other escapement monitoring techniques. Joint enhancement activities on the Stikine and Taku Rivers are also summarized.

The Transboundary Technical Committee (TTC) met prior to the season to update joint management, stock assessment and enhancement plans and determine forecasts for run strengths and initial total allowable catch (TAC) estimates for the various species and rivers. The results of this meeting are summarized in: Pacific Salmon Commission Transboundary Technical Committee. 2000. Salmon Management and Enhancement Plans for the Stikine, Taku and Alsek Rivers, 2000. Report TCTR 00-2.

Run reconstruction analyses are conducted on the sockeye salmon Oncorhynchus nerka runs to the 3 rivers for the purpose of evaluating the stocks and the fisheries managed for these stocks. No estimates of marine catch are made for Alaskan fisheries outside of District 106 and 108 for Stikine stocks, District 111 for Taku stocks and Subdistrict 182-30 \& 31 for Alsek stocks.

## STIKINE RIVER

Stikine River salmon are harvested by U.S. commercial gillnet fisheries in Alaskan Districts 106 and 108, by Canadian commercial gillnet fisheries located in the lower and upper Stikine River, and by a Canadian aboriginal fishery in the upper portion of the river. In addition, a Canadian terminal area fishery was operated in the lower Tuya River and/or at Tahltan Lake when escapements are estimated to be surplus to spawning requirements (ESSR) (Figure 1). A small sport fishery also exists in the Canadian sections of the Stikine drainage. In 1995, a United States personal use fishery was established in the lower Stikine River, no catches were reported in this fishery in 1995 through 2000. Additional catches of unknown quantity are taken in U.S. troll and seine fisheries and in sport fisheries near Wrangell and Petersburg. In 1996, the spring experimental troll area in the District 9 portion of Frederick Sound was expanded to target hatchery Chinook salmon O.tshawytscha; 4 previous areas were combined into 1 large area that also included previously unopened waters. This area was the same in 2000.

## Harvest Regulations and the Joint Management Model

Negotiations between Canada and the United States to replace expired portions of Annex IV, Chapter 1 of the Pacific Salmon Treaty resulted in the following arrangements for Stikine salmon which are expected to be in place for the 1999 to 2008 period:

## 1. General:

The Parties shall improve procedures for coordinated or cooperative management of the fisheries on transboundary river stocks. To this end, the Parties affirm their intent to
develop and implement abundance-based management regimes for transboundary Chinook, sockeye and coho salmon O. kisutch no later than May 1, 2004.

Figure 1. The Stikine River and principal U.S. and Canadian fishing areas.
(i) Assessment of the annual run of Stikine River sockeye salmon shall be made as follows:
a. a preseason forecast of the Stikine River sockeye salmon run will be made by the Committee prior to April 1 of each year. This forecast may be modified by the Committee prior to the opening of the fishing season;
b. inseason estimates of the Stikine River sockeye salmon run and the Total Allowable Catch (TAC) shall be made under the guidelines of an agreed Stikine Management Plan and using a forecast model developed by the Committee. Both U.S. and Canadian fishing patterns shall be based on current weekly estimates of the TAC. At the beginning of the season and up to an agreed date, the weekly estimates of the TAC shall be determined from the pre-season forecast of the run strength. After that date, the TAC shall be determined from the inseason forecast model;
c. modifications to the Stikine Management Plan and forecast model may be made prior to June 1 of each year by agreement of both Parties. Failure to reach agreement in modifications shall result in use of the model and parameters used in the previous year; and
d. estimates of the TAC may be adjusted in-season only by concurrence of both Parties' respective managers. Reasons for such adjustments must be provided to the Committee.
(ii) The Parties desire to maximize the harvest of planted Tahltan/Tuya sockeye salmon in their existing fisheries while considering the conservation needs of wild salmon runs. The Parties agree to manage the runs of Stikine River sockeye salmon to ensure that each country obtains $50 \%$ of the TAC in their existing fisheries. Canada will endeavor to harvest all fish surplus to escapement and broodstock needs returning to the Tuya and Tahltan Lake systems.
(iii) The Parties agree to continue the existing joint enhancement programs designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) Consistent with paragraph 1 above, the Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Stikine River. Assessment programs need to be further developed before a MSY escapement goal can be established.
(ii) In the interim, the United States' management intent is to ensure that sufficient coho salmon enter the Canadian section of the Stikine River to meet the agreed spawning objective, plus an annual Canadian catch of 4,000 coho salmon in a directed coho salmon fishery.
(3) Chinook salmon:
(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Stikine River are achieved.
(ii) The Parties agree that new fisheries on Stikine Chinook salmon will not be developed without the consent of both Parties. Consistent with paragraph 2, management of new directed fisheries will be abundance-based through an approach to be developed by the Committee. The Parties agree to implement assessment programs in support of the development of an abundance-based management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Stikine Chinook salmon by May 1999 and establish a new goal as soon as practicable thereafter.

As in most previous years, TTC met prior to the season to update joint management and enhancement plans, develop run forecasts and determine new parameters for input into the inseason run forecast model, referred to as the Stikine Management Model (SMM). The model was upgraded to provide inseason forecasts of the total Stikine sockeye salmon run as well as the following components of the run: the Tahltan stock (wild and planted combined); the planted Tuya stock; and the mainstem stocks. The model for 2000 was based on catch per unit effort (CPUE) data from 1985 to 1999 from District 106 and the Canadian commercial fishery in the lower river and from 1986 to 1999 from the lower Stikine test fishery. Linear regression was used to predict run size from cumulative CPUE for each week of the fisheries beginning in week 26 for all 3 fisheries. As in 1999, the intercept was forced to be zero in order to correct for a tendency to overestimate the run size in the earlier weeks during years of low abundance. New for the model in 2000 was a refinement to the lower Stikine commercial CPUE, which excluded catch and effort data from the Flood Glacier area, i.e. the new area introduced in 1997. In addition, the annual weekly CPUE values were increased by a factor of $1 / 0.75$ for years prior to 1994 to account for the extra gear allowed starting in that year. This made the historical CPUE data more comparable with the post1993 era. These modifications helped to correct the model for 1999 , which overestimated the run significantly.

In 2000, the preseason forecasts were used during week 26 (June 18-24) through week 27 (June 25 to July 01 ). After week 27 , inseason forecasts of total run size and TAC, produced by the SMM and based on CPUE data, were used to assist in determining weekly fishing plans (Table 1). The weekly inputs to the model included: the catch, effort, and stock composition (proportion Tahltan/Tuya from egg diameters, proportion planted Tuya from thermal mark analyses of otoliths) in the Canadian lower river test and commercial fisheries; the upper river catch in the aboriginal fishery (AF) and upper river commercial fishery; the catch, effort and assumed stock composition in Subdistrict 106-41; and, the catch and assumed stock composition in District 108 and Subdistrict 106-30. Results of thermal mark analyses were available inseason for the lower inriver fisheries to account for Tuya production in the model and reduce the risk of over-estimating the TAC of Tahltan sockeye salmon, which was predicted to be below average in 2000 .

Initially, average stock proportions in District 106 and 108 catches, from historical postseason scale pattern analysis (SPA), were assumed for weekly catches; the averages used each week depended upon whether the run was judged to be below average, average, or above average. The Tahltan/Tuya stock proportions were subsequently adjusted inseason based on the analysis of otolith samples taken in Districts 106 and 108. Inseason otolith sampling was conducted to estimate the contribution of planted Tahltan and Tuya Lake sockeye salmon to catches in these areas. The weekly estimate of Tuya fish in District 106-41 was added to the historical proportion of Tahltan fish in the SMM since this stock was not present in the historical database. No adjustments were made in District 108. Because different
proportions of Tahltan fish were observed in subdistricts of District 108, the overall contribution estimates for District 108 were weighted according to catches in the subdistricts.

Table 1. Weekly forecasts of run size and total allowable catch for Stikine River sockeye salmon as estimated inseason by the Stikine Management Model, 2000.

| Stat. Week | Start Date | Forecast <br> Run Size | TAC |  |  | Cumulative Catches |  |

${ }^{\text {a }}$ does not include test fishery catches

The preseason forecast for the Stikine was 138,000 sockeye salmon, which indicated a run size below the average of 200,691 fish (Appendix B.28). The forecast included 44,000 natural Tahltan sockeye salmon ( $32 \%$ ), 7,000 planted Tahltan fish ( $5 \%$ ), 21,000 planted Tuya sockeye salmon ( $15 \%$ ), and 66,000 mainstem fish ( $26 \%$ ). Canadian inseason predictions of total run ranged from 94,699 to 179,566 sockeye salmon; U.S. forecasts ranged from 140,980 to 182,956 sockeye salmon (Table 1). All forecasts indicated a below average run and the forecasts derived from inriver test fishery data were consistently well below those derived from commercial CPUE. The preseason forecast was more accurate than inseason forecasts in 2000. U.S. and Canadian weekly predictions differed due to different catch data input used for the updates.

Inseason management was influenced substantially by forecasts derived from the SMM, which was updated and refined by the TTC prior to the season. The model is based on the historical relationship between cumulative CPUE and run size and provides 3 sets of independently generated forecasts: 1 set based on US District 106 CPUE, another based on Canadian inriver commercial CPUE and the last based on Canadian test fishery CPUE. Each CPUE and run size dataset was significantly correlated; the forecasts used inseason each week are those derived from the dataset that has the highest correlation
coefficient for that particular statistical week. Unfortunately, the inseason forecasts exhibited a very wide range in 2000; the forecasts generated from the District 106 CPUE data were consistently higher than those derived from inriver CPUE data. The forecasts derived from the inriver test fishery data were consistently the lowest. However, historically the forecast that statistically has the best fit is the one derived from the inriver commercial fishery and it was this forecast that was used inseason (except for week 28 when the test fishery data was used). There was some comfort in using the forecasts derived from the inriver commercial CPUE since they tended to be mid-way between those developed from the other datasets.

Although the postseason estimates of run size and TAC were below the predictions that were used inseason for management. For example, the final inseason forecast generated by the SMM indicated a run size of 149,600 sockeye salmon and a TAC for Canada of 23,400 sockeye salmon. Run size and TAC projections from the SMM progressively decreased throughout the season from peak inseason estimates of 179,600 total run and 38,800 Canadian TAC in week 29 (July 09-15). The run forecasts during the peak of the fisheries (weeks 29 and 30) were more than twice the postseason run estimate. The TTC will review SMM performance prior to the 2001 fisheries and evaluate additional management tools.

## U.S. Fisheries

The 2000 harvest in the District 106 commercial gillnet fishery included 1,220 Chinook, 90,076 sockeye, 96,207 coho, 156,619 pink $O$. gorbuscha, and 199,836 chum salmon O. keta (Appendices A. 1 and B.1). In the District 108 fishery, 1,671 Chinook, 15,833 sockeye, 5,651 coho, 9,497 pink, and 40,337 chum salmon were harvested (Appendix A. 7 and B.7). The District 106 Chinook and chum salmon catches were average while the sockeye, coho, and pink salmon catches were below average (Appendix B.1). The District 108 Chinook salmon catch was above average and catches of the other species were below average. Alaskan hatchery fish contributed 1,724 fish ( $59.6 \%$ ) to the Chinook salmon catch, and 50,971 coho salmon $(50.0 \%)$ to the harvest from the 2 districts. The test fishery in District 108 caught 21 Chinook, 4,686 sockeye, 140 coho, 53 pink, and 724 chum salmon (Appendix A.9). Catches of each species in Districts 106 and 108 consist of fish of mixed stock origin; the contribution of Stikine stocks was estimated only for sockeye salmon. The proportions of Stikine sockeye salmon in the District 106 and 108 catches were estimated inseason using both the historical proportions of each stock and the proportions of thermally marked fish from fry plants to Tahltan and Tuya Lakes.

The postseason estimate of the contribution of Stikine sockeye salmon to the District 106 and 108 catches was 21,733 fish or $20.5 \%$ of the catch (Appendices A. 2 and A.8). The Sumner Strait fishery (Subdistricts $106-41 \& 106-42$ ) harvested 9,661 Stikine sockeye salmon (Appendices A. 4 and B.4), $16.7 \%$ of the total sockeye salmon harvest in that subdistrict, and the Clarence Strait fishery (Subdistrict 106-30) harvested 1,484 Stikine fish (Appendices A. 6 and B.6), $4.6 \%$ of the total sockeye salmon catch in that subdistrict. The District 108 fishery harvested 10,588 Stikine sockeye salmon (Appendix A.8), 66.9\% of the District 108 sockeye salmon catch.

The Districts 106 and 108 fishing seasons began on June 18 (week 26) and continued through September 19 (week 39). The initial opening in week 26 was for 2 days in both districts. The initial opening in District 106 was normally 2 days and any decision to extend fishing was based on fishery catch rates estimated by management biologists on site in the fishery. The estimated sockeye salmon CPUE in District 108 was above average for this week, but the District 106 sockeye salmon CPUE was half the average. Only 5 boats were fishing in Clarence Strait during this opening. The preseason forecast was used for the SMM and the otolith analysis in the prior week District 108 test fishery showed a Tuya:Tahltan ratio of approx. 50:50. The fishery was limited to 2 days in both districts because of the poor catch combined with the low preseason forecast of 51,000 Tahltan fish.

During week 27 (June 25-July 01) the fishery was open for 2 days. The sockeye salmon catches and CPUEs in both districts were above average. The effort in Clarence Strait was very low again this week with only 15 vessels reporting catches from that area. The good catches under normal, historical circumstances would have warranted a fishing time extension in both districts. However, the decision to not extend the fishing period was again based on the low Tahltan sockeye salmon forecast. Management remained conservative to lower the risk of overfishing the Tahltan stock if the inseason SMM overestimated the Tahltan sockeye salmon abundance.

During week 28 (July 02-08) District 106 and the southern portion of District 108 were open for 2 days. The northern section of District 108 (Frederick Sound) was closed. The decision to keep this portion of District 108 closed was based on the otolith analysis from both the District 108 test and commercial fisheries. Analysis indicated that Tahltan sockeye salmon were present at a higher proportion in the northern section of District 108 than in the southern section. The closed area would allow unimpeded migration of the Tahltan stock through a portion of the U.S. gillnet fishery in order to increase inriver escapement. The sockeye salmon CPUE in District 108 was above average and the District 106 CPUE was average. Under a less conservative fishing regime an extension or mid-week opening would have been allowed at this time to harvest the U.S. share of the Tahltan TAC which at this time was 14,664 fish. However, because of shortfalls in the Tahltan escapement during the past 3 years, no fishery extensions or mid-week openings were allowed.

During week 29 (July 09-15) 3 days were allowed in both districts. At the time the opening was announced the otolith sampling showed that there were no thermally marked Tahltan sockeye salmon in the Sumner Strait gillnet catch samples during the previous week and that Tuya sockeye salmon stock was still available in the fisheries. Three fishing days were given this week because abundance information indicated that the Tahltan run was large enough to ensure adequate escapement and that the majority of the fish had moved through the US fisheries. Also, with the low number of vessels fishing in District 106, it was likely that the US Tahltan TAC of 14,665 would not be exceeded.

During week 30 (July 16-22) both districts were open for 3 days. The 3 -day opening was based on the low number of marked Tahltan sockeye salmon in the catch, the low district effort, the inseason forecast of the Tahltan sockeye salmon escapement of 15,000 fish, and the U.S. total Stikine sockeye salmon TAC was 35,900 fish. The total U.S. Stikine sockeye salmon catch through week 29 was estimated to be 24,400 fish. A mid-week opening in District 108 was considered because of the high catches of mainstem sockeye salmon in the Canadian inriver fishery. However, no mid-week opening was allowed because the SMM Tahltan sockeye salmon run estimate had dropped to 29,580 fish since week 28 and the risk of overharvesting Tahltan sockeye salmon was too great.

During week 31 (July 23-29) both districts were initially open for 2 days. The sockeye salmon CPUE in Sumner Strait was slightly above average. However, with the low effort in District 106 the CPUE should have been even higher so an extension of both districts was not warranted. A 2-day mid-week opening was allowed in District 108. The SMM mainstem sockeye salmon run forecast was 90,000 fish and the U.S. TAC was 30,000 fish. Up to this time the combined district mainstem sockeye salmon catch was estimated at 6,850 and the otolith analysis showed no marked Tahltan sockeye salmon in any district catch since week 30 so a mid-week opening was justified.

Week 32 (July 30-August 05) was the final week of directed sockeye salmon fishing in Districts 106 and 108. Both districts were open for 2 days. The sockeye salmon catch in District 106 was near the average for this week, however, no extensions or mid-week openings were allowed because with the low effort the sockeye salmon CPUE should have been much greater.

The test fishery that was initiated in District 108 during 1998 and 1999 was undertaken again in 2000. Six gillnet vessels ( 3 in Frederick Sound and 3 in the Sumner Strait portion of District 108) were contracted to fish for up to 3 days for 3 consecutive weeks at specific locations of their choosing beginning on Tuesday, 16 June. Due to low catches during the first week an additional fourth fishing period was allowed to collect additional samples needed for adequate statistical analysis. Each of the vessels at each location fished different mesh sizes. The 3 sizes fished were: 4.625 in . to 4.875 in . ( 11.81 cm to 12.38 cm ); 5.375 in . to 5.25 in . ( 12.7 cm to 13.65 cm ); and 5.375 in . to 5.625 in . ( 13.65 cm to 14.29 cm ). The objective of the fishery was to see if the Tuya sockeye salmon stock was more susceptible to capture in a particular gillnet mesh size than other stocks were. This is of interest because age 2.2 fish are very rare in the Tahltan stock while they may represent $25 \%$ or more of the Tuya marine catch. Two-ocean age sockeye salmon are generally smaller than the 3-ocean fish and as such may be more susceptible to catch in smaller gillnets. If it could be shown that the Tahltan and Tuya stocks could be harvested at different rates then it may be possible to institute mesh size restrictions during years of low Tahltan runs to minimize the Tahltan stock catch while still fishing for the planted Tuya stock. Results after the first season did show a slight difference in the catch of age 2.2 sockeye salmon between mesh sizes with the smallest mesh size catching a higher percentage than either of the other mesh sizes. A total of 4,686 sockeye salmon were caught during the test fishery (Appendices A. 9 and B.9). Planted Tahltan fish made up $5.7 \%$, Tuya made up $31.0 \%$ and wild stocks made up the remaining $63.3 \%$ of the catch.

The management emphasis changed from sockeye salmon to pink salmon in week 33 (August 01-07). Pink salmon catches in both districts are not always a true reflection of abundance because the low pink salmon price, along with a high abundance of sockeye and coho salmon affect the fishing patterns and methods. During the 2000 season, the fishing effort in boat-days was $50 \%$ of average due to high chum salmon catches in other districts. Therefore, the total pink salmon catch also reflects low effort in Districts 106 and 108. Three-day fishing periods were allowed during weeks 33 and 34 (August 06-19) and a 2-day fishery was allowed for week 35 (August 20-26).

Coho salmon management in both the District 106 and 108 gillnet fisheries usually commences in late August or early September. During week 36 (August 27-September 02) the management emphasis changed from pink to coho salmon. The coho salmon catches prior to week 36 were below average due to a combination of late timing of the coho salmon run into inside waters, low coho salmon abundance, and low fishing effort in the districts. Two day openings were allowed in both districts from week 37 through week 39 (September 03-September 23). Both districts were closed for the season after week 39. Prior to the change to coho salmon management, the sockeye and pink salmon fisheries harvested 57,806 coho salmon, or $60 \%$ of the total District 106 coho salmon catch.

During the 2000 season, the District 106 gillnet fishery was open for a total of 33 days (Appendix A.5), and District 108 for 35 days (Appendix A.7). These were below the Districts 106 and 108 respective averages of 40 and 49 days (Appendices B. 5 and B.7). District 106 fishing effort in numbers of vessels was below average for the entire season. The number of vessels fishing in District 108 was below or near average for all openings except during week 31 (July 23-29) when a mid-week opening was allowed. The highest effort in number of boat-days in District 106 (282) and the greatest number of boats fishing occurred in week 29 when 94 boats fished for 3 days. The effort of 2,409 boat-days in District 106 was below average ( 4,213 boat-days; Appendix B.1). The 714 boat-days fished in District 108 were below average ( 1,522 boat-days; Appendix B.7). The low effort in both districts was due to a combination of low sockeye salmon catches and restricted fishing time in both districts and very good chum salmon fishing in other fishing districts near Juneau and Sitka.

## Canadian Fisheries

Catches from the combined Canadian commercial and aboriginal gillnet fisheries in the Stikine River in 2000 included: 3,086 large Chinook, 628 jack Chinook, 27,468 sockeye, 301 coho, 181 pink, and 144 chum salmon, and 103 steelhead trout O. mykiss (Appendices A.10, A.12, A.13, and B.17). In addition to these catches, 1,283 sockeye salmon were taken in an ESSR harvest in the Tuya River and 406 sockeye salmon were taken for samples at Tahltan Lake. Catches of all species except Chinook and pink salmon were below average (Appendices B.12, B. 14 and B.15). The final estimate of the total contribution of sockeye salmon from the Canada/U.S. fry-planting program to the combined Canadian aboriginal and commercial fisheries was 13,559 fish, $49.4 \%$ of the catch.

Three test fisheries (Chinook, sockeye and coho salmon) were conducted in the lower Stikine River in 2000, just upstream from the Canada/U.S. border. Combined test fishery catches included: 933 large Chinook (of which 226 were released alive), 18 jack Chinook, 2,378 sockeye, 436 coho, 34 pink, and 174 chum salmon, and 76 steelhead trout (Appendix A. 15 and B. 19). The objectives of the Chinook and coho salmon test fisheries were to obtain data for respective mark-recapture programs and to collect information about run timing. Additional objectives of the sockeye salmon test fishery were similar to those in previous years: to provide inseason catch, stock ID and effort data for input into the SMM to forecast the inriver run size; and, to determine migratory timing and stock composition of the sockeye salmon run for use in the postseason estimations of the inriver sockeye and coho salmon run sizes.

## Lower Stikine Commercial Fishery

Canadian commercial fishers in the lower Stikine harvested 1,970 large Chinook, 240 jack Chinook, 20,472 sockeye, 298 coho, 181 pink, and 144 chum salmon, and 89 steelhead trout in 2000 (Appendix A.10). The sockeye, coho, chum salmon and steelhead trout catch was below average (Appendix B.12). The catch of large Chinook and pink salmon was above average. The stock composition of the lower river sockeye salmon catch was: 801 planted Tahltan fish, $3.9 \%$ of the sockeye salmon catch; 4,364 wild Tahltan fish, $21.0 \%$ of the catch; 7,171 mainstem fish, $35.0 \%$ of the catch; and 8,136 planted Tuya fish, $39.7 \%$ of the catch (Table 2, Appendices A. 11 and B.13).

Weekly guideline harvests, based on SMM forecasts of the (TAC) apportioned by average run timing and domestic and international allocation agreements, were developed each week to guide management decisions during the sockeye salmon season. Particular attention was directed at the inriver run and escapement forecasts of the various stock groupings. Management through week 31 was focused primarily on the Tahltan sockeye salmon stock after which it switched to Mainstem sockeye salmon stocks through the end of August, and then to coho salmon. The Tahltan sockeye salmon stock was of particular concern given the preseason forecast of a below average run.

The fishery commenced at noon on Sunday, June 25 (week 27) for a scheduled opening of 2 days. The opening week for the fishery was roughly 1 week later than normal due to conservation concerns for Tahltan sockeye salmon. Although the overall sockeye salmon CPUE measured in sockeye/fisher/day (s/f/d) was above average, fishing time was kept to 48 hours due to the expectation of a below average run of Tahltan sockeye salmon. Stock composition data by the end of week 27 confirmed that the CPUE of Tahltan sockeye salmon was below average.

Table 2. Run reconstruction for Stikine sockeye salmon, 2000.

a Escapement into terminal and spawning areas from traditional fisheries.
b Catch allowed in terminal areas under the Excess Salmon to Spawning Requirement license.
c Fish returning to the Tuya system are not able to access the lake where they originated due to velocity barriers. d The number of Tuya fish that should be pass through traditional fisheries in order to harvest the Tuya stock at the same rate as the Tahltan stock to ensure adequate spawning escapement for Tahltan fish.
e Includes traditional, ESSR, and test fishery catches.
f Does not include ESSR or test fishery catches.
g U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than in the listed fisheries.

Sockeye salmon catches increased in week 28 (July 02-08) and the commercial CPUE increased to 257 $\mathrm{s} / \mathrm{f} / \mathrm{d}$, which was a record high value for this week, and the highest of the season. Again, concern over a potentially weak Tahltan sockeye salmon run kept fishing time to 2 days. The SMM forecast for week 28, based on the inriver test fishery CPUE indicated a TAC of only 3,000 Tahltan Lake sockeye salmon, which was to be split 50/50 between Canada and the U.S. Stock ID information indicated the CPUE of Tahltan sockeye salmon was slightly above average, $105 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ vs $101 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ average. However, updated
forecasts of the total inriver Tahltan run from the SMM ranged from 32,000 sockeye salmon based on test fishing data, to 47,000 sockeye salmon based on commercial fishery data. Run size projections in this range indicated an allowable lower river catch range of 0 to 13,000 Tahltan sockeye salmon for the season and a guideline catch through week 28 of 0 to 7,600 fish. The estimated cumulative Tahltan sockeye salmon catch through week 28 was 2,400 fish, which was towards the lower end of this range.

In week 29 (July 09-15), fishing time was again limited to 2 days. Results from otolith analyses from samples collected over the previous weeks continued to indicate a high contribution of Tuya sockeye salmon to the lower Stikine catches. This meant the excellent catches and high CPUE observed to date were wholly attributed to sockeye salmon production from the Tuya Lake fry plants. The overall sockeye salmon CPUE in week 29 was again above average, although it dropped to $167 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ from the peak value in week 28. Forecasts of the inriver Tahltan sockeye salmon run were updated with information gathered just prior to the opening. The inriver run forecast decreased to a range of 15,000 to 33,000 Tahltan sockeye salmon. The cumulative harvest of 3,100 Tahltan fish through week 29 continued to fall well within the guideline harvest range of 0 to 4,900 sockeye salmon.

Concern over decreasing inriver Tahltan run forecasts and decreasing Tahltan Lake weir projections lead to a reduction in fishing time in week 30 (July 16-22) to a total of 30 hours. The overall sockeye salmon CPUE for the first 24 hours was above average and rising, and the proportion of small-egged fish (Tahltan and Tuya sockeye salmon) dropped to $38 \%$. Prior to this week, the Tahltan/Tuya contribution was $75 \%$ or higher. Because of the declining Tahltan/Tuya contribution to the catch and a Mainstem sockeye salmon CPUE that was above average, a 6 -hour extension was given to target mainstem stocks, which normally peak in week 30 . Projections of the inriver Tahltan run continued to decrease to the range of 14,000 to 27,000 sockeye salmon and forecasts of the number of fish to reach the Tahltan Lake weir ranged from 5,000 to 17,000 sockeye salmon. The estimated cumulative catch of Tahltan sockeye salmon in the lower river through week 30 was 3,700 fish out of a total catch of 16,100 sockeye salmon. Normally, $90 \%$ of the Tahltan run was through the lower river fishery by the end of week 30 .

In week 31 (July 23-29), the fishery was initially posted for 30 hours to obtain data regarding the Tahltan/Tuya composition and the strength of the Mainstem run. The catch for the first 24 hours was 750 sockeye salmon for 11.5 fishers and the proportion of Mainstem fish had increased to $79 \%$. The fishery was extended to 3 days as a result of the decreasing contribution of Tahltan/Tuya stocks, and an opportunity to make up some of the apparent shortfall in the Mainstem catch. Inriver forecasts of the Mainstem run ranged from 28,000 (test fish data) to 70,000 (commercial data) and the guideline harvest range through week 31 for mainstem sockeye salmon was 5,000 to 25,000 fish. Through week 31, the cumulative catch stood at 5,114 mainstem sockeye salmon

Weekly fishing times continued to be restricted to 2 days/week for weeks 32 through 36 (July 30September 02) as attention shifted to Mainstem stocks. Weekly forecasts of the inriver Mainstem run showed a broad range, for example 38,000 to 68,000 fish in week 33 , depending upon which input data was used, i.e. test fish CPUE vs commercial CPUE. Low sockeye salmon counts a Tahltan Lake weir suggested the forecasts derived from commercial data, which were to be the preferred forecasts in 2000 according to the joint Canada/US management plan, were grossly overestimating the inriver run strength. As a result, conservative openings were maintained through the remainder of the season even as fishing effort dropped to 6 fishers, from week 35 on. Below average coho salmon catches provided little incentive for fishers to remain in the fishery after week 37 (September 03-09) which marked the end of the season.

Based on sockeye salmon CPUE in the lower river, the overall sockeye salmon run timing appeared to be about normal; the run peaked in week 28 , similar to average. The Tahltan stock peaked in weeks 27 and 28 , and the Tuya stock peaked in week 28 ; normally they peak over weeks 27 and 28 . Mainstem sockeye salmon peaked in week 30 , again normal timing for this stock conglomerate.

As in recent years, Excess Salmon to Spawning Requirements (ESSR) fishing activities again focused on the lower Tuya River to harvest fish returning from the fry-planting program. A total of 1,283 sockeye salmon was harvested in this area (Table 2, Appendix B.18). However, due to the low numbers of fish at Tahltan Lake, there was no ESSR harvest of sockeye salmon at Tahltan Lake in 2000. A total of 406 sockeye salmon was sampled at the weir for stock ID data; after sampling, these fish were given to the Tahltan FN.

Out of 18 licenses available for the lower river, 13 licenses were issued in 2000 with a maximum of 12 licenses being active in any one week. The total effort in terms of boat-days was 227, below average of 394 boat-days (Appendix B.12). As in 1999, each fisher was allowed the use of two gillnets of which one could be a drift net. A maximum mesh size restriction of 150 mm through July 16 was implemented to reduce the incidental catch of Chinook salmon. In 1997, the upstream fishing boundary for the lower river fishery was moved 25 km upstream to Flood River to increase the fishing area over previous years. The same area has been fished since that time.

## Upper Stikine Commercial Fishery

A small commercial fishery has existed near Telegraph Creek on the upper Stikine River since 1975. The catches recorded in 2000 included: 7 large Chinook salmon, 2 Chinook jacks, and 889 sockeye salmon which were all below average (Appendices A. 12 and B.14). The fishing effort was below average with an average of only 2 fishers fishing 1 to 2 days per week. A total of 9.3 days was fished and the total effort amounted to 19.8 boat-days. For comparison, the average fishing time was 25 days with an average effort of 38 boat-days.

## Aboriginal Fishery

The Stikine aboriginal fishery, which is located near Telegraph Creek, harvested 1,109 large Chinook, 386 jack Chinook, and 6,107 sockeye salmon (Appendix A 13, B 15); all were above average (Appendix B 15). As in past years, fishing times were not restricted in this fishery.

## Escapement

## Sockeye

A total of 6,076 sockeye salmon was counted through the Tahltan Lake weir in 2000 which was below average of (Appendices A. 17 and B.22). An estimated 1,230 fish (20.2\%) originated from the fry planting program. The estimate of planted fish in 2000 was based on the proportion of thermal marked Tahltan sockeye salmon as determined from otoliths from a random sampling of 406 fish collected at the weir. In addition, 1,717 sockeye salmon were collected for broodstock for the fry-planting project. This leaves a spawning escapement of 3,953 sockeye salmon (Table 2 ) of which 3,152 were wild fish and 801 were thermally marked. The weir count was well below the goal of 24,000 sockeye salmon.

The spawning escapements for the Mainstem and the Tuya stock groups are estimated indirectly by computing the ratio of Tahltan to Mainstem and Tuya components in the total inriver sockeye salmon run. Stock identification data are collected in the lower river commercial and test fisheries. The ratios of Tahltan:Mainstem and Tahltan:Tuya are applied to the estimated inriver Tahltan run size to develop an estimate of the total inriver sockeye salmon run. The escapements are estimated by subtracting the inriver catches from the inriver run estimate. The escapement estimates are 10,132 Mainstem and 7,091 Tuya sockeye salmon. The Mainstem sockeye salmon stocks spawn in tributaries and the mainstem of the

Stikine River. The Mainstem spawning escapement was below the escapement goal range of 20,000 to 40,000 fish. Aerial survey results also indicated a below average escapement of mainstem sockeye salmon; however, survey conditions were very poor at several of the spawning sites. The Tuya fish are blocked from entering potential spawning grounds of the Tuya tributary by natural barriers and are targeted in the ESSR fishery, which caught 1,283 fish in 2000. The fate of the remaining 5,808 Tuya fish is uncertain. In 1998, 28 Tuya sockeye salmon were radio tagged and released at the ESSR fishing site, located near the mouth of the Tuya River. All but 1 tagged fish moved downstream. Several fish were tracked to the Tahltan River. The majority of fish were tracked downstream to a final location near the mouth of the Scud and Porcupine rivers. One fish was tracked downstream to a location below the Canada/US boundary. It was not known if any of the tagged fish successfully spawned.

A new sockeye salmon mark-recapture program was initiated in 2000 to explore the feasibility of developing an alternate abundance-based management regime for Stikine sockeye salmon stocks. The estimate of the above-border run using a Darroch estimate was 121,746 sockeye salmon $\mathrm{SE}=12,936 \mathrm{CI}=$ $96,391-147,100$. The mark-recapture estimate is higher than the inriver run estimate of 53,145 sockeye salmon, which is based on the traditional method of reconstructing the inriver Tahltan run then expanding it using stock ID and run timing data. Further analysis is required to investigate why the estimates are so far apart.

## Chinook

Chinook salmon escapement was enumerated at the Little Tahltan weir; 6,631 large fish and 108 jack Chinook salmon were counted between June 23 and August 18 (Appendices A. 19 and B.25). The escapement for large Chinook salmon was above the upper end of the escapement goal range; 3,300 point goal, with a range of 2,700 to 5,400 fish.

Aerial surveys of the Tahltan River and Beatty Creek have been discontinued. The peak survey count at Andrew Creek was 583 large Chinook (Appendix B.26), salmon well within the escapement goal range of 325 to 750 fish. The aerial survey count for the Little Tahltan River was 2,720 or $41.0 \%$ of the weir count.

A mark-recapture study was conducted again in 2000. The escapement estimate for large (non jacks) Stikine River Chinook salmon was 27,531 fish ( $\mathrm{m}=612, \mathrm{C}=3,657, \mathrm{R}=73$ ) (Appendix B.26). The Little Tahltan escapement of 6,631 represents $24 \%$ of the total escapement. The escapement goal for the Stikine River Chinook salmon (revised in 1999) is 17,500 fish, with a range of 14,000 to 28,000 Chinook salmon.

## Coho

Test fishery cumulative weekly CPUE of coho salmon was close to record low and $20 \%$ of the cumulative weekly sockeye salmon CPUE, thus indicating the coho salmon run to be $20 \%$ of the estimated sockeye salmon run of 69,700 fish or 13,900 coho salmon. Based on these analyses, the total inriver escapement of Stikine River coho salmon was 13,212 fish. This escapement was below the interim escapement goal range of 30,000 to 50,000 and represents $45 \%$ of the average escapement of 29,300 fish. Coho salmon aerial surveys were incomplete due to extremely poor viewing conditions at several of the spawning sites. Using only the spawning sites where reliable counts were taken, the runs were near record low with only 306 coho salmon observed.

A new coho salmon mark-recapture program was initiated in 2000 to explore the feasibility of developing an alternate abundance-based management regime for Stikine coho salmon. The estimated total escapement using a modified Peterson estimate ( $\mathrm{m}=609, \mathrm{r}=15, \mathrm{c}=686$ ) was 25,500 coho salmon, ranging from 13,700 to 55,812 fish. The low catch in both the test and commercial fisheries in tandem with the low number of tagged fish recovered, resulted in the very wide range of coho salmon escapements as
indicated above. Increased fishing effort both at the tagging and recovery site (commercial and test fishing grounds) are recommended for future studies.

## Sockeye Run Reconstruction

The postseason estimate of the Stikine sockeye salmon run size was 78,504 fish, of which 19,143 are of Tahltan origin (wild \& planted), 34,034 are of Tuya origin (fry from Tahltan broodstock planted into Tuya Lake), and 25,327 are Mainstem stocks (Table 2, Appendix B.28). These estimates are based on postseason data including otolith recovery and analysis in the U.S. Districts 106 and 108 catches; scale pattern analysis of marine harvests; otolith analysis, egg-diameter stock-composition estimates for inriver catches from the Canadian commercial, aboriginal, ESSR, and test fishery catches; and escapement data. The 2000 total run was below the average run of 200,691 sockeye salmon and $56.9 \%$ of the preseason forecast of 138,000 sockeye salmon (Table 1).

## TAKU RIVER

Taku River salmon are harvested in the U.S. gillnet fishery in the Alaskan District 111, in northern Southeast Alaska seine and troll fisheries, and in the Juneau area sport fishery and inriver personal use fishery (Figure 2). Canadian fisheries for Taku River salmon include a commercial gillnet fishery located in the river near the Canada/U.S. border, an aboriginal fishery, and a sport fishery.

## Harvest Regulations

New fishing arrangements were in place in 1999 as a result of negotiations between Canada and the United States of Annex IV, Chapter 1 of the Pacific Salmon Treaty. The arrangements that are expected to apply to the Taku River for the 1999 to 2008 period are as follows:
(1) Sockeye salmon:
(i) Except as noted below, Canada shall harvest no more than $18 \%$ of the TAC of the wild sockeye salmon originating in the Canadian portion of the Taku River each year;
(ii) If the projected inriver escapement is greater than 100,000 sockeye salmon, Canada may, in addition, harvest $20 \%$ of the projected inriver escapement above 100,000 sockeye salmon;
(iii) The Parties agree to manage the runs of Taku River sockeye salmon to ensure that each country obtains catches in their existing fisheries equivalent to each country's share of wild sockeye salmon and a $50 \%$ share of fish originating from Taku fry plants;
(iv) The Parties agree to continue the existing joint Taku enhancement program designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) The Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Taku River no later than May 1, 2004. The Parties commit to developing a revised MSY escapement goal to be implemented no later than May 1, 2004.

Figure 2. The Taku River and principal U.S. and Canadian fishing areas.
(ii) Until a new abundance-based approach is developed, the management intent of the United States is to ensure a minimum above-border inriver run of 38,000 coho salmon, and the following arrangements will apply:
a. no numerical limit on the Taku River coho salmon catch will apply in Canada during the directed sockeye salmon fishery (through week 33);
b. if in-season projections of above-border run size are less than 50,000 coho salmon, a directed Canadian harvest of up to 3,000 coho salmon is allowed for assessment purposes as part of the joint Canada/US Taku River mark-recapture program;
c. if in-season projections of above-border run size exceed 50,000 coho salmon, a directed Canadian harvest of 5,000 coho salmon is allowed;
d. if in-season projections of above-border run size exceed 60,000 coho salmon, a directed Canadian harvest of 7,500 coho salmon is allowed;
e. if in-season projections of above border run size exceed 75,000 coho salmon, a directed Canadian harvest of 10,000 coho salmon is allowed.
(3) Chinook salmon:9
(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Taku River are achieved.
(ii) The Parties agree that new fisheries on Taku River Chinook salmon will not be developed without the consent of both Parties. Management of new directed fisheries will be abundancebased through an approach to be developed by the Committee no later than May 01, 2004. The Parties agree to implement assessment programs in support of the development of an abundancebased management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Taku River Chinook salmon by May 1999 and thereafter establish a new goal as soon as practicable.

## U.S. Fisheries

The 2000 traditional District 111 drift gillnet salmon fishery was open for a total of 40 days from June 18 through September 26 (Appendix C.1). Effort levels were very high during the summer fishery, including a record 152 boats fishing in week 30. As a result of low effort in the fall fishery, fishing effort for the entire season totaled 2,915 boat-days and was below of average (Appendix D.1). Actual on-the-grounds fishing effort was less as the result of industry decisions; processors imposed catch limits for chum salmon on individual boats in weeks 28 and 29 , forcing some fishermen to miss fishing time in those weeks.

The commercial salmon harvests in the traditional fishery totaled 1,137 Chinook, 168,272 sockeye, 7,546 coho, 54,716 pink, and 668,595 chum salmon (Appendix C.1). Catches of Chinook, coho, and pink salmon were all below average (Appendix D.1). The sockeye salmon catch was above average and was the third largest on record and the chum salmon catch was nearly 3 times the average.

Hatchery stocks contributed substantially to the harvests of both sockeye and chum salmon and minor numbers to the harvest of other species. Sockeye salmon from joint U.S./Canada Taku River fry planting programs contributed an estimated 1,580 fish (1.0\%) to the traditional District 111 fishery harvest (Appendices C. 3 and D.2). U.S. domestic hatchery sockeye salmon stocks contributed an estimated 26,851 fish $(16.0 \%)$, and included a small number of thermally marked fish from a fry-planting program at Chilkat Lake in upper Lynn Canal. Wild sockeye salmon contributed an estimated 130,132 fish (77.3\%) from the Taku River and 9,709 fish (5.8\%) from Port Snettisham. Sockeye salmon harvests in the Speel Arm THA were composed almost entirely of domestic hatchery fish. Alaskan hatchery Chinook salmon contribution was 465 fish as estimated by coded wire tag (CWT) analysis; $40.9 \%$ of the harvest.

The harvest of 168,272 sockeye salmon in the traditional fishery was above average. Weekly sockeye salmon catches were above average throughout the summer season. Domestic hatchery sockeye salmon started to contribute to the traditional fishery in mid-July (week 29) and peaked from late July through mid-August. Fishing effort in Stephens Passage was above average as a result of fishermen targeting hatchery sockeye and Limestone Inlet chum salmon.

The catch of 668,595 chum salmon in the traditional fishery was composed almost entirely (>99\%) of summer chum salmon (Appendix D.1). The summer chum salmon catch of 665,582 was the highest on record and 2.9 times the average. The summer chum salmon run is considered to last through mid-August (week 33) and is composed mostly of domestic hatchery fish, with small numbers of wild stock fish contributing to the harvest. Chum salmon returning to Douglas Island Pink and Chum, Inc. (DIPAC) hatcheries in Gastineau Channel and to the DIPAC remote release site at Limestone Inlet contributed a major portion of the catch but quantitative contribution estimates are not available. The catch of 3,013 fall chum salmon (i.e., chum salmon caught after week 33) was below average. Most of these chum salmon are of wild origin.

The 2000 season was the first year of large returns of adult hatchery sockeye salmon back to DIPAC Snettisham Hatchery located inside Port Snettisham. These fish contributed substantially to the catches in the traditional District 111 gillnet fishery and to catches in extended openings in the Speel Arm Terminal Harvest Area (THA) near the hatchery. The THA was open for 23 days and catches totaled 29 Chinook, 17,656 sockeye, 282 coho, 3,980 pink, and 1,399 chum salmon. Due to the terminal nature of THA catches, harvests and effort from the THA are not included elsewhere in this report.

The District 111 pink salmon harvest of 54,716 fish was below average (Appendix D.1). Runs of pink salmon to most streams in the district, including the Taku River, were poor.

Coho salmon stocks harvested in District 111 include runs to the Taku River, Port Snettisham, Stephens Passage, and local Juneau area streams as well as Alaska hatchery fish. The coho salmon catch of 7,546 fish in the traditional fishery was below average (Appendix D.1). Coho salmon catches were well below average during each week of the fishing season and were the lowest on record for a number of weeks in the early portion of the fishery. Alaskan hatchery coho salmon contributed 519 fish or $6.9 \%$ of the District 111 harvest (Appendix C.1), a similar percentage to 1999 but down substantially from previous years even though runs to local Alaska hatcheries were good. Although inriver Taku coho salmon abundance estimates were below average during most of the season, post-season analysis indicates the escapement goal was surpassed.

Management actions used to conduct the District 111 drift gillnet fishery were limited to imposing restrictions in time, area and gear. In the first week of the season, week 26,3 days fishing time was allowed in both Taku Inlet (Subdistrict 111-32) and Stephens Passage (Subdistrict 111-31). The sockeye salmon catch in week 26 was a record respective to the week, so fishing time was increased to 4 days for the next week. Fishing time remained at 4 days for week 28 because the mark-recapture estimate of the above border Taku sockeye salmon run size was well above average. Projections of the run size decreased beginning late that week and, with the exception of the Speel Arm THA, fishing time was limited to 2 or 3 days per week for the remaining 5 weeks of the summer fishing season in order to keep the cumulative catch within the projected U.S. TAC of Taku sockeye salmon (Table 3).

In order to increase sockeye salmon spawning escapements to Tatsamenie Lake, which experienced low escapements in 1998 and 1999, U.S. and Canadian fishery managers agreed during preseason management consultations to limit fishing time in the drift gillnet fishery in Taku Inlet and in the

Table 3. U.S. inseason forecasts of total run size, inriver run size, TAC, and the U.S. harvest of Taku River sockeye salmon for 2000.

| Stat | Total <br> Run | Inriver <br> Run | Total <br> TAC | U.S. <br> TAC | Projected <br> U.S. Harvest |

| 31 | 220,912 | 103,938 | 145,912 | 119,648 | 115,474 |
| 32 | 220,695 | 109,146 | 145,695 | 119,470 | 110,050 |
| 33 | 240,900 | 125,953 | 165,900 | 136,038 | 113,447 |

Inseason U.S. TAC calculated as $82 \%$ of the total TAC.
Canadian inriver gillnet fishery to a maximum of 3 days per week during weeks 31 through 33 . Extensions of fishing time in these areas could occur but only after consultation and agreement between fishery managers of the two countries. Management of the fishery in Taku Inlet in 2000 abided by this agreement, with fishing time limited to 2 days per week in weeks 31 and 32 and 3 days in week 33 .

During the summer fishing season, fishing time and gear allowed in Stephens Passage south of Circle Point differed slightly from that in Taku Inlet in order to offer additional opportunity to harvest the large run of hatchery summer chum salmon. A 6-inch minimum mesh size restriction was employed during July in Section 11-B south of Circle Point. This allowed harvest of hatchery chum salmon from the Limestone Inlet remote releases while limiting harvest rates on wild sockeye salmon stocks. Lower Stephens Passage (Subdistrict 111-20) was not opened to fishing this year because there was not a harvestable surplus of pink salmon. Port Snettisham (Subdistricts 111-33/-34/-35) was closed to fishing through August 7 to limit harvest rates on wild Crescent and Speel sockeye salmon runs. By early August, assessment programs indicated good escapements to both Crescent and Speel Lakes and, beginning August 8 portions of Port Snettisham were opened to fishing each week to harvest sockeye salmon returning to the Snettisham Hatchery. The Speel Arm THA was opened continuously from August 10 until September 5.

The fall fishing season in District 111 lasted seven weeks, from August 13 (week 34) through September 26 (week 40). In the first week of the fall season, fishing time was set at 3 days in Stephens Passage and 2 days in Taku Inlet in order to minimize fishing on a perceived weak Taku coho salmon run and yet continue to allow additional opportunity to harvest hatchery sockeye salmon in Stephens Passage and inside Port Snettisham. With the exception of extended fishing time in the Speel Arm THA, fishing time throughout the district was limited to 2 days per week for the remainder of the season. This course of action was taken to conserve both Taku coho and fall chum salmon stocks, and continued even when mark-recapture estimates of the Taku River coho salmon run size indicated the escapement goal would likely be met or exceeded.

Several other fisheries in the Juneau area harvested transboundary Taku stocks in 2000. Personal use harvests reported for the Taku River included 21 Chinook, 930 sockeye, 25 coho, 59 pink and 5 chum salmon (Appendix D.4). The spring Juneau-area sport fishery harvested an estimated 2,613 large Chinook ( 28 inches or longer) and 122 small Chinook salmon. Of the large fish, 911 ( $35 \%$ ) were wild mature, none were wild immature and $1,702(65 \%)$ were hatchery fish (CWT estimate). A number of stocks are thought to contribute to the sport fishery, including those from the Taku, Chilkat, and King Salmon rivers, and local hatchery stocks, but the major contributor of large, mature fish is believed to be the Taku River. The July Hawk Inlet shoreline purse seine fishery north of Point Marsden in Chatham Strait was not opened this year due to weak returns of early run pink salmon to the Juneau area.

## Canadian Fisheries

Taku River commercial fishery harvest was 28,009 sockeye, 4,395 coho, 1,576 large Chinook, 87 jack Chinook (fish less than 2.3 kg ), and 192 steelhead salmon in 2000 (Appendix C.4). Catches of steelhead trout and Chinook salmon were above average, catches of sockeye salmon were average, and catches of coho and Chinook jack salmon were below average. Sockeye salmon originating from fry plants contributed an estimated 436 fish to the catch, comprising $1.6 \%$ of the total sockeye salmon harvest (Appendix D.6). A total of 39 days was fished and seasonal fishing effort of 351 boat-days; both were average. Both set and drift gill netting techniques were used with the majority of the catch taken in drift gillnets. Mesh sizes were restricted to less than 150 mm through July 16 to minimize the incidental catch of Chinook salmon. In addition to gillnetting, 1 fish wheel was in operation for a small portion of the fishing season.

In addition to the commercial catches, 50 Chinook, 140 sockeye and 342 coho salmon were harvested in the aboriginal fishery in 2000 (Appendix D.7). The average catches in the Taku aboriginal fishery have included 61 Chinook, 237 sockeye, 108 coho, and 1 chum salmon and 2 steelhead trout.

The Canadian preseason forecast was for a run of 273,000 sockeye salmon, which was the average of a sibling-based forecast of 311,600 sockeye salmon and a forecast of 234,700 sockeye salmon based on stock-recruitment data. The point estimate was above the previous average run (Canadian estimate). The preseason forecast was used to guide weekly management actions for the first week of the season; thereafter, inseason forecasts based on the joint Canada/U.S mark-recapture program at Canyon Island were used (Table 4).

Table 4. Canadian inseason forecasts of total run size, total allowable catch (TAC), and spawning escapement of Taku sockeye salmon, 2000.

| 33 | 282,285 | 207,285 | 87,459 | 37,311 | 32,678 | 26,044 |
| 34 | 282,285 | 207,285 | 97,982 | 37,311 | 34,811 | 27,186 |

According to the postseason run estimate of 236,377 sockeye salmon the Canadian catch (excluding test fishery catches) of 28,149 sockeye salmon represented $18.0 \%$ of the TAC.

For coho salmon, the preseason outlook was for an average run due to good smolt numbers encountered in the 1999 coded-wire tagging program. The final inseason forecast of the inriver run ranged from 70,005 to 82,276 coho salmon. According to PST provisions, the Canadian allowable catch after week 33 was 7,500 to 10,000 salmon. Of the total commercial catch, 3,326 coho salmon were caught after week 33
(Appendix C.4); all of the coho salmon catch in the Aboriginal fishery occurred after week 33. The combined commercial and AF post week 33 catch was 3,668 coho salmon.

DFO funded a creel census on the Nakina River in 2000 to obtain information on the sport catch and effort on this system. Results indicate a total catch of 688 Chinook of which 604 ( $87.8 \%$ ) were released and 8 steelhead salmon which were all released.

Two test fisheries were in operation in 2000: 1 which operated May 1 to June 17 to sample for tagged Chinook salmon, and the other, which operated September 14 to October 6 to sample for tagged coho salmon. Total test fishery landings included 1,312 large Chinook, 87 jack Chinook, 319 sockeye, 710 coho salmon, and 19 steelhead trout (Appendices C. 7 and D.8). An additional 493 large female Chinook salmon were released.

The commercial fishery commenced at noon on Sunday, June 18 (week 26) for a scheduled opening of two days. Although the commercial sockeye salmon CPUE was slightly above average, the fishing period was kept to 48 hours to reduce the incidental catch of Chinook salmon.

As in previous years, cumulative guideline harvests were developed each week to guide weekly management decisions so that: a) the catch was consistent with conservation and Treaty goals; and b) management was responsive to changes in forecasts of abundance, i.e. abundance based. The guidelines were based on current inseason forecasts of the Canadian sockeye salmon TAC (based on mark-recapture estimates) apportioned by historical run timing. In weeks 27 and 28 (June 25 -July 01 and July 02-08), fishing times were scheduled for 3 days per week in response to the weekly guidelines. Total run forecasts for these weeks were 200,710 and 193,739 sockeye salmon, respectively. The cumulative harvest through week 28 was 6,776 versus the cumulative guideline of 6,406 sockeye salmon. CPUE values for these weeks ranged from above average in week 27 to below average in week 28 .

The run forecasts used in week 29 (July 09-15) and week 30 (July 16-22) increased to a range of 251,875 to 253,799 sockeye salmon, respectively, and total season spawning escapement predictions ranged from 96,603 to 99,034 sockeye salmon. Weekly fishing times were initially posted at 3 days, however a 1 -day extension was provided in each week to attempt to harvest some of the surpluses indicated by the weekly guideline harvests. Additional time over and above the 4 days was not fished because of below average CPUE in the last day of fishing in each week. By the end of week 30 , the cumulative catch of 15,119 sockeye salmon (Appendix C.4) was below the guideline of 17,163 sockeye salmon.

In preseason planning consultations with the US, it was agreed that special efforts would be undertaken by both Parties in 2000 to increase the spawning escapement of Tatsamenie sockeye salmon over recent years. The Canadian management plan specified that for weeks 31 through 33, fishing time would be limited to a maximum of 3 days/week. This management action was to be accompanied by similar restrictions in the U.S. District 11 fishery. Extensions of fishing time above prescribed levels in each country's fisheries would only be considered after consultation and agreement between fishery managers of the two countries. So, as per the plan, fishing times were limited to 3 days/week for weeks 31-33. A Tulsequah flood essentially washed out the fishery in week 31 (July 23-29). Effort levels dropped from 10 fishers in day 1 to 4 fishers in day 3 and catches were poor due to high water and heavy debris loads. The peak weekly catch ( 5,504 sockeye salmon) and CPUE (149 sockeye/fisher/day) of the season occurred the following week at which time the CPUE was above average and above average CPUE continued through week 33. After week 33 (August 06-12), the cumulative catch was 26,044 sockeye salmon compared to the guideline harvest of 32,678 sockeye salmon. During this period, the catch had fallen further below the guideline harvest because of the Tulsequah flood and because of the commitment to limit fishing time to address Tatsamenie escapement rebuilding.

Despite the overall shortfall in the catch compared to the guideline harvest, fishing time was kept to 3 days in week 34 (August 13-19) due to declining sockeye salmon abundance as evidenced by below average commercial sockeye salmon CPUE, declining fish wheel catches of sockeye at Canyon Island and concerns over below average early season coho salmon abundance. Week 34 essentially marked the end of the sockeye salmon season.

The cumulative commercial sockeye salmon CPUE over the season totaled 848 sockeye/fisher/day and was average. Overall run timing appeared to be normal to slightly later than normal, and there appeared to be 3 distinctive peaks in weeks 27, 30 and 32 . The peak CPUE of the season occurred in week 32, which was two weeks later than normal. The strength of the peak in week 32 and its later than normal timing were likely attributable to the Tulsequah flood which occurred in week 31. Typically, the Tulsequah flood causes a pause in upstream migration and a buildup of sockeye salmon in the lower reaches of the river that pulses up the river after the floodwaters subside.

After week 34, management attention shifted to coho salmon and to forecasts of the inriver run into Canada. The fishery in week 35 (August 20-26) was open for 4 days; effort level had dropped to 8 fishers and fishing conditions were adversely affected by high water. The catch of 874 coho salmon this opening was within the guideline harvest range of 490 to 1,469 coho salmon developed for this week. Through week 35, the weekly CPUE in the commercial fishery was consistently below average and inriver run projections assuming the run was on time or 1 week late, ranged from 31,250 to 61,419 coho salmon. According to the PST harvest sharing arrangements, this meant that the Canadian seasonal quota after week 33 was in the range of 3,000 to 7,500 coho salmon.

There was no significant change in the inriver run forecasts used for management in week 36 (August 27September 02 ); it ranged from 40,619 to 60,271 coho salmon. Fishing time was initially posted at 2 days due to uncertainty about run timing and below average CPUE the previous week. However, improvements in CPUE early in the opening lead to a 1-day extension. This brought the post week 33 cumulative catch to 2,775 coho salmon, which was within the range suggested by the guideline harvest ( $1,671-5,012$ ). At this point, it appeared that the run timing was somewhat later than normal and therefore, the upper range of the inriver forecast and guideline harvest range, which were derived from a "one-week late scenario" indicated additional fishing time was warranted after week 36.

With fishing effort reduced to 3 fishers, fishing time during week 37 (September 03-09) was increased to 4 days, although there was no fishing activity on day 4 . The coho salmon CPUE during this last opening dropped by $45 \%$ over the previous week and was below average. Although the inriver run forecasts justified additional fishing periods after week 37, the fishery was vacated due to the lack of a buying operation.

The cumulative coho salmon CPUE through week 37 was below average. The strength of the early part of the run, through week 35 , appeared to be below average, whereas, after the end of August, run strength appeared to be about average.

## Escapement

## Sockeye

Spawning escapement of sockeye salmon in the Canadian portion of the Taku River drainage was estimated from the joint Canada/U.S. mark-recapture program. Counting weirs operated by Department of Fisheries and Oceans, Canada (DFO) at Little Trapper and Tatsamenie lakes provide information on the distribution and abundance of discrete spawning stocks within the watershed. The Taku River Tlingit First Nation (TRTFN) additionally conducted a sockeye salmon enumeration program at Kuthai Lake.

A mark-recapture program has been operated annually from 1984 to 2000 to estimate the above-border run size (i.e., border escapement); spawning escapement was then estimated by subtracting the inriver catch. The 2000 estimate of above-border run was 103,735 sockeye salmon and the spawning escapement was estimated at 75,267 fish (Table 1; Appendices C. 8 and D.9). This spawning escapement was below average and was close to the mid-point of the interim escapement goal range of 71,000 to 80,000 sockeye salmon.

The escapement through the Little Trapper Lake weir was 11,551 sockeye salmon and was average (Appendices C. 10 and D.10). The run was comprised of 4,921 females ( $42.6 \%$ of total) and 6,630 males ( $\mathrm{n}=740$ ).

The Tatsamenie Lake weir count in 2000 was 7,575 sockeye salmon (Appendix C.9) and the spawning escapement was 5,570 . This was above the average (Appendix D.10). The sex composition was $65.8 \%$ female i.e. 4,990 fish ( $\mathrm{n}=750$ ). A total of 1,119 females and 886 males were held for broodstock; eggs/ milt were taken from 765 females and 684 males. The total broodstock holding mortality was 18 females and 14 males. On October 16, 336 females and 188 males were released because the egg take target had been exceeded. The spawning success of the released fish is unknown.

The sockeye salmon count through the Kuthai Lake weir was 4,096 fish (Appendix C.11) and was below average (Appendix D.10). An estimated 2,607 females contributed to the run ( $n=610$ ), which equates to a sex composition of $64 \%$ female.

## Chinook

Aerial surveys of large Chinook salmon (3-ocean and larger) to the 6 escapement index areas annually surveyed by ADF\&G were as follows: Nakina 2,907 fish, Kowatua 702 fish, Tatsatua, 953 fish, Dudidontu 482 fish, Tseta 160 fish, and Nahlin 728 fish (Appendix D.12). The total of 5,932 large Chinook salmon observed was below average and was the second lowest count obtained during this period.

A carcass weir was again operated by the TRTFN on the Nakina River to obtain tag and age-length-sex data on Chinook salmon. A total of 658 Chinook salmon was observed at the weir. As in 1999, the Nahlin River weir was not installed in 2000 due to concerns that it would impede Chinook salmon migration.

## Coho

Spawning escapement of coho salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tag application and recovery occurred through the early part of week 41 (October 01-07). The recovery effort consisted of commercial, test, and aboriginal fisheries. The above-border escapement was estimated to be 70,147 fish and the spawning escapement
was estimated at 64,700 fish (Appendix C. 7 and D.13). The spawning escapement was below average but above the interim escapement goal of 27,500 to 35,000 fish.

## Pink

A total of 6,529 pink salmon was counted at the Canyon Island fish wheels in 2000. (Appendix D.15). There was no program in place to estimate the escapement of pink salmon to the Taku River in 2000. The pink salmon count at the fish wheels was below average.

## Chum

There was no program in place to estimate the system-wide escapement of chum salmon. A total of 423 chum salmon was captured in the Canyon Island fish wheels and was average (Appendix D.15).

The Taku River fall chum salmon run has been depressed since 1988. It is unlikely that the spawning escapement goal of 50,000 to 80,000 chum salmon was achieved in 2000.

## Steelhead

There was no program in place to estimate the system-wide steelhead salmon escapement. An escapement goal has not been set for this species. A total of 160 steelhead salmon were caught in the Canyon Island fish wheels in 2000; above average (Appendix D.15).

## Sockeye Run Reconstruction

The postseason estimate of 130,132 wild Taku sockeye salmon in the District 111 fishery (Table 5) was estimated from the analysis of scale patterns, brain parasite prevalence, and thermal marks. The estimate of 279 marked Trapper Lake and 1,301 marked Tatsamenie Lake sockeye salmon in the District 111 catch was based on expansion of otolith marked sockeye salmon recovered in the District 111 fishery. The U.S. inriver personal use fishery harvested an additional 930 sockeye salmon. The otolith mark rate in the inriver sockeye salmon fishery during the month of July, when the personal use fishery is open, was applied to this catch, indicating that 11 of these fish were marked. The estimated total U.S. harvest of Taku sockeye salmon was 132,642 fish (Table 5).

The estimate of the magnitude of the above-border sockeye salmon run in 2000 , based on the joint Canada/U.S. mark-recapture program, was 103,735 fish (Table 5). By subtracting the Canadian inriver catch of 28,468 sockeye salmon (in commercial, aboriginal and test fisheries) from the above-border run estimate results in an above-border escapement estimate of 75,267 fish.

The run size estimate, determined by summing the estimated U.S. harvest and the above-border run, was 236,377 sockeye salmon, which was average. Based on the escapement goal range of 71,000 to 80,000 fish, the TAC was $156,377-165,377$ sockeye salmon, of which the U.S. harvested $84.8 \%$ and Canada harvested $18.0 \%$ (Table 5). The overall exploitation rate was estimated to be $67.1 \%$ in 2000.

Table 5. Taku sockeye salmon run reconstruction, 2000. Estimates do not include spawning escapements below the U.S./Canada border.

#### Abstract

ALSEK RIVER

Alsek River salmon stocks contribute to the U.S. commercial gillnet fisheries located in Dry Bay, at the mouth of the Alsek River (Figure 3). Unknown quantities of Alsek origin fish are also taken in the U.S. commercial gillnet and troll fisheries in the Yakutat area. No commercial fishery exists in the Canadian portions of the Alsek River drainage, although aboriginal and recreational fisheries occur in the Tatshenshini River and some of its headwater tributaries.

## Harvest Regulations \& Management Objectives

Although catch sharing of Alsek salmon stocks between Canada and the U.S. has not yet been specified, Annex IV does call for the development and implementation of cooperative abundance-based management plans and programs for Alsek Chinook, sockeye and coho salmon. Interim escapement goal ranges for Alsek sockeye and coho salmon were initially set by the TTC at 33,000 to 58,000 sockeye salmon, and 5,400 to 25,000 coho salmon. However, stock assessment projects to determine system-wide escapements have not yet been developed. Instead, the principle escapement-monitoring tool for Chinook, sockeye, and coho salmon stocks on the Alsek River is the Klukshu weir, operated by DFO and the Champagne-Aishihik First Nation. The weir has been in operation since 1976. To make the management objectives of Chinook and sockeye salmon better defined in terms of Klukshu stocks, revised goals, expressed in terms of Klukshu stocks only; were established for 2000.

The initiative to establish a specific Klukshu Chinook salmon spawning goal began in 1991 when the TTC set an interim spawning objective of 4,700 Klukshu Chinook salmon. This goal was based more on manager's intuition than on science. From 1995 through 1997, the TTC reviewed this escapement level and concluded that goal of 4,700 Chinook salmon was not supported by the data. A new goal range of 1,100 to 2,300 fish was proposed based on joint analyses of stock-recruitment data. The Parties conducted independent internal reviews of the analyses. Although there was not unanimous support for the proposal, there was agreement on establishing a minimum goal consistent with the lower end of the proposed range. As a result, Canadian and U.S. managers agreed to a minimum spawning escapement goal of 1,100 Chinook salmon for the Klukshu system for the 2000 season.

The principal escapement-monitoring tool for Chinook salmon stocks on the Alsek River is the Klukshu weir, operated by DFO and the Champagne-Aishihik First Nation (CAFN). A joint report that recommends a biologically-based escapement goal for the Klukshu stock was completed in June, 2000. Based on that report Canadian and U.S. managers have set a spawning escapement goal range of 7,500 to 15,000 sockeye salmon for 2000.

Since 1998, mark-recapture estimates of total inriver abundance of Alsek River Chinook salmon are available. A pilot mark-recapture program was initiated for Alsek River sockeye salmon in 2000.

## Preseason Forecasts

The overall sockeye salmon run to the Klukshu River in 2000 was predicted to be below average in strength. Principal contributing brood years to the 2000 run were 1995 (Klukshu escapement of 19,817 sockeye salmon) and 1996 (Klukshu escapement of 7,891 sockeye salmon); average Klukshu escapement was 14,703 fish. Based on historical stock-recruitment analysis, the range of Klukshu escapements that appear most likely to produce maximum sustained yields is 7,500 to 15,000 sockeye salmon.

The 2000 overall Alsek sockeye salmon run was forecast to be 40,000 sockeye salmon. This estimate was based on: a predicted run of 22,300 Klukshu sockeye salmon derived from historical Klukshu stockrecruitment data; an assumed Klukshu contribution to the total run of $35 \%$; and an adjustment factor of 0.64 to account for the tendency of the method to over predict the Klukshu weir counts since 1995. A run size of this magnitude is below the average of 64,000 sockeye salmon (based on the Klukshu weir count expanded by $1 / 0.35$ to account for other inriver escapement and an assumed U.S. harvest rate of 0.20 ).

Figure 3. The Alsek River and principal U.S. and Canadian fishing areas.

The Klukshu early sockeye salmon run escapements in 1995 and 1996 were 2,289 and 1,502 , respectively. Both years were below average but the predominant brood year (1995) was close to the optimum level of 2,500 sockeye salmon spawners as determined through separate stock-recruitment analyses by DFO of the early run. Normally this would support an expectation for an above average run. However, returns in 1998 and 1999 were far below expectations that were developed in a similar manner. Therefore the early run was predicted to be at best, average.

The Klukshu Chinook salmon escapements in 1995 and 1996, 5,400 and 3,400 Chinook salmon, respectively, were above average with the 1995 escapement being the highest on record. However, the escapements were above the optimum escapement range of 1,100 to 2,300 Chinook salmon as determined from current stock-recruitment analysis. As a result, the preliminary outlook was for a below average run.

The coho salmon escapements observed at the Klukshu River in 1996 (3,500 coho salmon) and 1997 (300 coho salmon but incomplete count) suggests the run in 2000 would be average to above average. The average escapement was 2,607 coho salmon.

## U.S. Fisheries

The Dry Bay commercial set-gillnet fishery harvested 677 Chinook, 9,522 sockeye, 5,103 coho, 5 pink and 130 chum salmon (Appendix E.1). The fishery was open for 37 days which was below average (Appendix E.4). The majority of fishing time ( 24 days) occurred late in the season (mid-August through early October) after the sockeye salmon run had largely passed through the fishery. The total number of days fished during the bulk of the sockeye salmon run was 13. The total effort expended in the fishery was 307 boat-days; below average. The estimate of subsistence harvests included 36 Chinook, 81 sockeye, and 29 coho salmon (Appendix E.5).

The Alsek sockeye salmon harvest of 9,522 fish was below average (Appendix E.4). There was no reported harvest from the Alsek surf area in 2000. Adjustments to the weekly fishing periods during the sockeye salmon season relied heavily on fishery performance data; the decision of whether or not to extend any given period was initially based on catch and CPUE data gathered inseason during that particular period. From week 30 through 34, management was also based on Klukshu weir sockeye salmon counts. The Alsek management model was not used this year as a management tool because of unreliable run estimates produced in recent years.

Historically, a set-gillnet fishery targeting on Chinook salmon was conducted during May and early June. Due to depressed runs, the directed fishery has been closed since 1963 and Chinook salmon have only been harvested incidentally during the sockeye salmon fishery in early June. From 1963 through 1997, the early June periods were limited in time in order to reduce the impact on Chinook salmon. With the advent of the new Chinook salmon escapement goal concern for incidentally caught Chinook salmon has diminished so the management of the early June periods was based on sockeye salmon CPUE. Gillnet mesh size was restricted to a maximum of 6 inches through July 1. The Chinook salmon harvest of 677 fish was above average (Appendix E.4); $94 \%$ of the Chinook salmon catch ( 636 fish) was taken during the first 3 weeks of the season.

The Alsek River was opened to commercial fishing during week 25, the second Monday in June (June 12). The fishery typically opens by regulation on the first Monday in June but based on the preseason projection and poor sockeye salmon returns in 1999 the fishery was managed very conservatively in 2000. The initial opening in week 25 was limited to 24 hours in order to evaluate Chinook and sockeye salmon run strengths. Fishery performance (CPUE) indicated that the sockeye salmon harvest was well above historical levels and fishing time was extended 1 day. Week 26 (June 18-24), CPUE continued well above average so fishing time was again extended to 48 hours. Fishing time was decreased to 24 hours during weeks 27 (June 25-July 01) and 28 (July 02-08) in spite of well above average CPUE specifically to protect Klukshu River sockeye salmon. Fishing time was limited to 24 hours during each of the next 3 weeks due to below average CPUE. In early August, during week 32 (July 30-August 05) fishing time was increased to 48 hours due to above average CPUE values. Fishing time was again restricted to 1 day during weeks 33 (August 06-12) and 34 (August 13-19) due to below average CPUE values.

The coho salmon harvest of 5,103 fish was below average (Appendix E.4). Escapement of coho salmon at the Klukshu weir was well above average early in the season and fishing periods ranged from 3 to 4 days during weeks 35 through 41.

## Canadian Fisheries

The aboriginal fishery harvested an estimated 65 Chinook and 745 sockeye salmon (Appendices E. 2 and E.6). The catch of Chinook salmon was the second lowest on record and the sockeye salmon catch was the fourth lowest on record. The catch of of 51 coho salmon was above average.

Catches in the Tatshenshini recreational fishery were also below average with an estimated 44 Chinook, 129 sockeye, and 0 coho salmon being harvested (Appendices E. 2 and E.6). The low Chinook salmon catches were attributed to usually high water conditions throughout the summer fishing season. In additional, extensive closures implemented to address conservation concerns for sockeye salmon resulted in the low catch of sockeye and coho salmon. The catch data was derived from a creel census program conducted in the Dalton Post area by the Klukshu weir personnel.

Management of salmon in the Yukon is a shared responsibility between DFO and the Yukon Salmon Committee (YSC). The YSC was established in 1995 pursuant to the Comprehensive Land Claim Umbrella Final Agreement between the Government of Canada, the Council for Yukon Indians and the Government of the Yukon. The Committee is a public board consisting of 10 members, $70 \%$ of which are appointed by Yukon First Nations. Two CAFN members sit on the YSC. Although the Committee currently operates by consensus, the voting structure of the Committee is organized so that, should a vote be necessary, $50 \%$ of the votes reside with appointees of Yukon First Nations.

The 2000 Alsek-Tatshenshini management plan, adopted by CAFN, YSC, and DFO, was based on the objectives described in the Harvest Regulations \& Management Objectives section above. For Chinook and early sockeye salmon management, the status of the Klukshu weir counts was to be reviewed on or about July 18 to ensure weir and spawning escapement targets were on track. The status of the late sockeye salmon run would be reviewed the first week of September. Adjustments to inseason fishing regimes in the sport and aboriginal fisheries would be made if deemed necessary. Other key elements of the plan are described below.

The center of aboriginal fishing activity in the Alsek drainage occurs at the Champagne/Aishihik First Nation village of Klukshu, on the Haines road, about 60 km south of Haines Junction. Salmon are harvested by means of gaff and traditional fish traps as the fish migrate up the Klukshu River into Klukshu Lake. The fishing plan for the aboriginal fishery in the Klukshu River for the period prior to August 15 allowed fishing by means of fish traps for 2 days per week. After August 15, it was planned that the traps would be fished 3 days per week. Conservation thresholds that might invoke restrictions in the Aboriginal fishery were projected Klukshu weir counts of $<1,100$ Chinook and $<1,500$ early sockeye salmon. Gaff fisheries also exist on Village Creek and in the headwaters of the Tatshenshini River and tributaries thereof (Goat Creek, Stanley Creek, Parton River, and the Blanchard River). The plan did not restrict the gaff fishery other than to reserve Goat Creek, Stanley Creek, and the Parton River for elders only.

The majority of the sport fishing effort on this drainage occurs on the Tatshenshini River, at and just downstream of the mouth of the Klukshu River in the vicinity of the abandoned settlement of Dalton Post. The management plan prohibited the retention of sockeye salmon in the recreational fishery prior to August 15 unless the weir count projection for the early run was $>4,500$ sockeye salmon. The Chinook salmon daily catch limit was 1 fish and the possession limit was 2 Chinook salmon. For other salmon species, the daily catch and possession limits were 2 , and 4 , respectively. However, the aggregate limit for all salmon combined was 2 salmon per daily, 4 in possession. Sport fishing in the Dalton Post area was initially to be open from 6:00 am Saturday to 12:00 noon Tuesday each week. Headwater areas upstream of the British Columbia/Yukon border were to be closed for the season to protect spawning Chinook salmon. Conservation thresholds that were expected to invoke additional restrictions in the sport fishery
were projected Klukshu weir counts of $<1,500$ Chinook and $<10,600$ sockeye salmon (early and late runs combined).

The Yukon Salmon Committee introduced a mandatory Yukon Salmon Conservation Catch Card (YSCCC) 1999, which was required by all salmon sport fishers in 2000. The purpose of the YSCCC is to improve harvest estimates and to serve as a statistical base to ascertain the importance of salmon to the Yukon sport fishery. Anglers are required to report their catch via mail by the late fall. Information requested includes: the number, sex, size, date and location of salmon caught and released.

Stock status reviews conducted mid-late July raised conservation concerns for sockeye salmon when projections, based on weir counts to date and historic timing data, suggested that the weir objectives for sockeye salmon were not likely to be achieved. As a result of these concerns, the non-retention for sockeye salmon in the sport fishery was extended, initially through September 30, and then to October 31.

CAFN also imposed substantial closures in the aboriginal fishery. The trap fishery did not open in 2000 and on September 12, fishing in the lower Klukshu River downstream of the weir was closed weekly from 12:00 noon Tuesdays to 06:00 am Saturdays. For the fourth consecutive year, depleted runs and closures in the aboriginal fishery seriously impacted CAFN fishers, resulting in basic needs levels not being achieved. In addition to poor salmon abundance, fishing conditions throughout the season were hampered by usually high water conditions.

## Escapement

It is currently not possible to accurately assess whether the system-wide escapement goals for Alsek Chinook, sockeye, and coho salmon are being met because total drainage enumeration programs are not established. An unknown and presumably variable proportion of the escapement of each species is enumerated at the weir on the Klukshu River (Appendices E. 3 and E.7). Current escapement monitoring programs including the Klukshu weir, Village Creek electronic counter, and aerial surveys do, however, allow annual comparisons of escapement indices (Appendices E.8-E.10). The most reliable comparative escapement index for Alsek drainage salmon stocks is the Klukshu River weir count. Escapements for 2000 are given in Table 6.

Table 6. Catch and Klukshu index escapement data for Alsek sockeye, Chinook, and coho salmon for 2000.

|  | Sockeye | Chinook | Coho |
| :--- | ---: | ---: | ---: |
| Escapement Index a |  |  |  |
| $\quad$ Klukshu Weir Count | 5,551 | 1,365 | 4,832 |
| Klukshu Escapement | 5,422 | 1,321 | 4,791 |
|  |  |  |  |
| Harvest b |  |  |  |
| U.S. Commercial | 81 | 36 | 5,103 |
| U.S. Subsistence | 0 | 58 | 29 |
| Canadian Sport | 745 | 65 | 1 |
| Canadian Aboriginal | 10,348 | 836 | 5,184 |
| $\quad$ Total |  |  |  |

${ }^{\text {a }}$ Klukshu River salmon stocks represent an assumed large and variable portion of the total Alsek River salmon escapement.
${ }^{\mathrm{b}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

A mark-recapture program to estimate the drainage wide escapement of Chinook salmon in the Alsek River was initiated in 1998 and has been conducted each year since that time. During the first year of the program a radio telemetry program was also conducted in addition to the mark-recapture program to estimate spawning distribution. Data from these programs will substantially improve our knowledge of the overall escapement and distribution of Alsek River Chinook salmon stocks.

A new pilot-level mark-recapture program for sockeye salmon was initiated in the Alsek River in 2000. The objective of this program was to obtain postseason estimates of total sockeye salmon abundance for the Alsek River. Sockeye salmon were captured in the lower river, just above the uppermost commercial fishery site, tagged, and released. Tag recovery efforts were conducted in upriver spawning areas including Klukshu River weir, Neskataheen Lake, and other known sockeye salmon spawning sites located in the Tatshenshini River drainage.

## Sockeye

Klukshu River sockeye salmon weir count was 5,551 with an escapement of 5,422 fish (Table 6, Appendix E.7), and consisted of a below average count of 237 early-run fish (count through August 15) and a below average count of 5,314 late-run sockeye salmon. The total escapement was $72.2 \%$ of the lower end of the recommend escapement goal range of 7,500 to 15,000 fish. The sockeye salmon count at Village Creek was 2,222 fish which was below average (Appendix E.8).

A new sockeye salmon mark-recapture program was initiated in 2000 to explore the feasibility of developing an abundance-based management regime for Alsek sockeye salmon. The final estimate of the inriver run using a modified Peterson estimate was 37,887 sockeye salmon ( $\mathrm{m}=956, \mathrm{r}=21$, $\mathrm{c}=885$ ), with a $95 \%$ CI of 23,410 to 52,365 fish. The spawning escapement was estimated to be 37,142 fish. The Klukshu escapement therefore represents $15 \%$ of the total Alsek River escapement, substantially below previously published contributions that ranged from $37 \%$ to $60 \%$. The estimated contribution of Neskataheen sockeye salmon to the total Alsek run was $6 \%$. It is recommended for future studies that increased effort be directed at recovering Alsek sockeye salmon on the spawning grounds, thus providing for a more reliable escapement estimate.

Aerial surveys of 3 Alsek index tributaries were conducted and all were below average. The mainstem Tatshenshini, from the Alsek and Tatshenshini rivers confluence up to the water survey station immediately below Village Creek, count was 176 sockeye salmon. The count was 25 sockeye salmon in Basin Creek and 180 sockeye salmon in the Tanis River.

## Chinook

The most reliable comparative Chinook salmon escapement index for the Alsek drainage is the Klukshu weir count. The Chinook salmon weir count was 1,365 and escapement count was 1,300 fish (Table 6, Appendix E.3) and both were below average (Appendix E.7). The escapement count was within the escapement goal range of 1,100 to 2,300 Klukshu Chinook salmon and represents $15 \%$ of the total escapement.

Based on mark-recapture study, the spawning escapement estimate for Alsek River large Chinook salmon was 9,182 fish ( $m=469, \mathrm{C}=509, \mathrm{R}=24$; Appendix E.10). The inriver run past Dry Bay was estimated to be $8,432(6,805-14,308)$ fish.

Three aerial Chinook salmon surveys were conducted and all were below average (Appendix E.9). The Chinook salmon counts were 152 in the Takhanne River, 163 in Blanchard River, and 33 Goat Creek. Surveys were conducted during poor viewing conditions.

## Coho

The Klukshu weir count was 4,832 and escapements count was 4,791 coho salmon were both above average of (Table 6, Appendix E.7). The weir was removed prior to the completion of the coho salmon return and typically does not include fish that migrate after mid-October. (Appendix E.3)

## Run Reconstruction

Estimates of the Klukshu contribution to the sockeye salmon run to the Alsek drainage vary from $15 \%$ based on mark-recapture results, $37 \%$, as estimated from an ADF\&G mark-recapture study in 1983, to $60 \%$, based on Canadian fishery managers' professional judgment. The Klukshu weir count divided by the estimated proportion of Klukshu fish that constitute the total Alsek run, minus the recreational and aboriginal fishery catches, yields an escapement estimate for the Alsek River. The estimated escapement added to the U.S. commercial and subsistence catches yields an estimate of the entire Alsek run. The mark-recapture estimate of 38,000 fish for the entire Alsek drainage was within the escapement goal range. Using the $37 \%$ to $60 \%$ contribution range, the estimated sockeye salmon escapement in the Alsek River was on the order of 8,200 (Canada) to 13,800 (U.S.) fish and the estimated Alsek sockeye salmon run was on the order of 17,700 (Canada) to 23,300 (U.S.) sockeye salmon. The sockeye salmon escapement estimate falls well below the low range of the sockeye salmon escapement goal range of from 33,000 (U.S.) to 58,000 (Canada) for the Alsek River.

## ENHANCEMENT ACTIVITIES

## Egg Collection

In 2000, sockeye salmon eggs were collected at Tahltan Lake on the Stikine River for the thirteenth year, and in the Tatsamenie Lake system on the Taku River, for the eleventh year. No eggs have been collected at Little Trapper Lake on the Taku River since 1994.

## Tahltan Lake: Target 6.0 million eggs

The egg collection was contracted to Arc Environmental Ltd. for the fifth consecutive year. Lower than average escapement in year 2000 made capture of broodstock relatively difficult in comparison with previous years that had higher escapement levels. An estimated 2.39 million eggs were collected from 841 females and 825 males. The total estimated egg collection is based on an average historical fecundity of 2,900 eggs per female. An additional 27 females and 12 males were rejected due to spent gametes (males), immature eggs (females), internal bleeding and disease symptoms. The broodstock was collected by beach seine at the major spawning site as has been done in previous years. The eggs were collected over the course of eleven egg-take days of which 4 loads of eggs were delayed in shipment to the hatchery.

## Tatsamenie Lake: Target 3.0 million eggs

Egg collection was again contracted to B. Mercer and Associates Ltd. A total of 765 females and 684 males were spawned. An estimated 2.62 million eggs were collected from the 765 females (based on a
measured average fecundity of 4,083 eggs per female). Of the total fertilized eggs collected, 2.57 million were delivered to Snettisham hatchery in 6 shipments, and 244,000 were placed in a passive flow incubator at Tatsamenie Lake.

Tatsamenie Lake broodstock was again captured at an adult enumeration weir that was located at the outlet of Tatsamenie Lake. This was the seventh year that all of the Tatsamenie broodstock was captured at this location. The required broodstock was collected between August 19 and September 5. A total of 1,119 females and 886 males were held prior to the first egg take on September 17. On Oct. 16, 336 females and 188 males were released after the egg take goal was reached. The spawning success of the released fish is unknown.

## Incubation, thermal marking, and Fry Plants (1998 Brood Year)

The egg incubation and thermal-marking program at Snettisham Hatchery went smoothly in year 2000. Snettisham hatchery is operated by DIPAC, a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Incubation of 1999 brood eggs took place at Snettisham Hatchery and the resultant fry were transported to the appropriate systems from May 20 to June 26, 2000. The infectious hematopoietic necrosis (IHN) virus was not detected during the incubation period for the Tahltan and Tatsamenie fry.

## Tahltan Lake

A total of 2.2 million fry from the 1999 Tahltan sockeye salmon egg take was planted back into Tahltan Lake in 2000. Survival from green-egg to outplanted fry was $80.4 \%$. Fry outplanting took place from May 20 through May 27.

## Tuya Lake

A total of 0.9 million fry from the 1999 Tahltan sockeye salmon egg take were planted into Tuya Lake in 2000. Survival from green-egg to outplanted-fry was $82.3 \%$. Fry outplanting took place from June 23 to June 26.

## Tatsamenie Lake

A total of 0.35 million fry from the 1999 egg-take was planted into Tatsamenie Lake in 2000. Survival from green-egg to outplanted-fry was $75.9 \%$. Outplanting took place on June 1 .

## Outplant Evaluation Surveys

## Acoustic and Trawl, Beach seine and Limnological Sampling

Standard limnological surveys were conducted at Tatsamenie, Tuya, and King Salmon Lakes by B. Mercer \& Associates Ltd. and by PBS personnel. Limnological and beach seine surveys were performed at Nakina Lake by Brian Mercer and at Tahltan Lake by onsite DFO personnel.

## ADF \&G Thermal Mark Laboratory

During the 2000 season, ADF\&G Thermal mark lab received 16,888 sockeye salmon otoliths collected by ADF\&G port sampling staff as part of the U.S./Canada Enhancement program. These collections came
from commercial and test fisheries in U.S. waters and in Canadian fisheries on the Taku and Stikine Rivers over a 13 -week period. In addition, cost recovery and rack samples from Snettisham Hatchery as well as several escapement samples were examined. Combined, the laboratory processed 15,252 of the otoliths received ( $90.3 \%$ ) and provided estimates on hatchery contribution for 136 distinct sampling collections. Of these totals, 4,422 otoliths were identified and classified as belonging to 1 of 36 marking groups. Contribution estimates on the percentage of enhanced fish in the commercial openings were provided to ADF\&G and Canadian fisheries managers within 24 to 48 hours after sampling.

## Canadian Thermal Mark Laboratory

Sub-samples of juvenile and adult otolith samples that were collected during the 2000 season were analyzed at the DFO otolith lab in Whitehorse.

## APPENDICES

Appendix A. 1. Weekly salmon catch in the Alaskan District 106 commercial drift gillnet fisheries, 2000.
Catches do not include Blind Slough terminal area harvests.
Effort may be less than the sum of effort from 106-41\&42 and 106-30 because some boats fished in more than one subdistrict.
Large Chinook are MEF length $\geq 660$.

| Week | Start <br> Date | Catch |  |  |  |  | Effort |  |  |

Appendix B. 1. Salmon catch and effort in the Alaskan District 106 commercial drift gillnet fisheries, 19602000.

Effort may be less than the sum of effort from 106-41/42 and 106-30 since some boats fished in more than one subdist Large Chinook are MEF length $\geq 660$.

${ }^{\text {a }}$ Jacks as reported by fishery and loosely based on "small" fish $\sim 2.5-3.0 \mathrm{~kg}$ until 2000 .
Estimated jack catch based on sampling, i.e. jack<660 mef or <735 fl. Post 2000
the jack catch was based on sampling. A jack chinook is defined as a chinook < 660 MEF or 735 FL
${ }^{\text {b }} 1987$ jack chinook catch was for both set and drift nets.
${ }^{c}$ Catch of large fish includes 226 released fish in 2000.

Appendix B. 20. Sockeye salmon stock proportions and catch by stock in the test fishery in the lower Stikine River, 1985-2000.
Stock composition date from; scale pattern analysis 1985; average of scale pattern analysis and GPA 1986-1988;
egg diameter and thermal mark otoliths 1989-2000.

Appendix D. 1. Salmon catches and effort in the Alaskan District 111 and Subdistrict 111-32 (Taku Inlet) commercial drift gillnet fishery, 1960-2000.
Chinook are MEF length $\geq 660$.
Days open are for the entire district and include openings to harvest spawner chinook salmon, 1960-1975.

Appendix D. 4. Salmon catch in the U.S. subsistence and personal use fisheries in the Taku River, 19672000.

The subsistence fishery was open 1967 to 1976 and 1985 and the personal use fishery was open 1989-2010.
The harvests are miminum estimates because not all permits are filled out and returned.

${ }^{\text {a }}$ Incomplete harvest data.
${ }^{\mathrm{b}}$ In addition to these fish, 180 adult female chinook, one adult male chinook and four steelhead were captured and released live.
${ }^{\text {c }}$ In addition to these fish 439 adult female chinook were captured and released live.

Appendix D. 9. Taku River sockeye salmon run size, 1984-2000.
Run estimate does not include spawning escapements below the U.S./Canada border. The early season sockeye expansion
is based on the proportion of fish wheel sockeye catch that occurs before the fishery opens.

Appendix D. 10. Sockeye salmon escapement estimates of Taku River and Port Snettisham sockeye salmon stocks, 1979-2000.

| Spawners equals escapement to the weir minus fish collected for brood stock. |  |  |  |  |  |  |  |  |  |  |

${ }^{\text {a }}$ From 1999-2000 to determine the number of large fish in the Canadian harvest, the average \% of large fish (75\%) was applied to all catches except the recreational catch, which is assumed to be $100 \%$ large and comprise 300 fish annually.
${ }^{\mathrm{b}}$ U.S. catch includes D111 commercial gillnet and Juneau area sport fishery harvests; the estimate of large fish for the commercial fishery includes age-1.3 and older fish;
all sport harvests are assumed to be large fish.

${ }^{\text {a }}$ Counts include small Chinook salmon.
${ }^{\mathrm{b}}$ Weir was removed prior to the end of the coho run.
${ }^{c}$ The chinook and sockeye escapements into Klukshu Lake are calculated from the weir count minus fish harvested above the weir site minus broodstock taken. The remainder of the food fishery harvest occurred below the weir, at Village Creek, and Blanchard and Takhanne Rivers.
${ }^{\mathrm{d}}$ Includes sockeye counts up to and including August 15.

Appendix F. 1. Tahltan Lake egg collection, fry plants, and survivals, 1989-2000.
Number for eggs and fry are millions. Eggs collected from Tahltan broodstock are used for outplants
to both Tahltan and Tuya Lakes.

Multiple Release Treatments

[^13]
[^0]:    ${ }^{a}$ All Tahltan includes wild and thermally marked fish.

[^1]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.

[^2]:    ${ }^{\text {a }}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

[^3]:    ${ }^{\text {a }}$ Catch of large fish includes 226 released fish in 2000.

[^4]:    ${ }^{\text {a }}$ A total of 842 females and 836 males was taken for broodstock ( 39 rejects included in the broodstock total).
    ${ }^{\text {b }} 406$ fish were sacrificed for otolith analysis.
    ${ }^{c}$ weighted proportion of wild to hatchery Tahltan fish from the weir samples applied to number of spawners

[^5]:    ${ }^{\text {a }}$ All Tahltan includes wild and thermally marked fish.

[^6]:    ${ }^{\text {a }}$ Data not available to estimate contributions of pink salmon from Alaska hatcheries.

[^7]:    ${ }^{\text {a }}$ All Tahltan includes thermally marked fish.

[^8]:    ${ }^{\text {a }}$ There was no commercial fishery in 1984.

[^9]:    ${ }^{\text {a }}$ Average proportions were from averages of weekly estimates.

[^10]:    Daily counts unavailable.
    ${ }^{\mathrm{b}}$ A slide occurred blocking the entrance for a while.

[^11]:    ${ }^{\mathrm{a}}$ There was no test fishing during statistical weeks 29-37 inclusive.

[^12]:    ${ }^{\text {a }}$ Aboriginal catch by week is not available.

[^13]:    ${ }^{\text {a }}$ Eggs not transported but placed in inlake incubator; $2000=244,000$
    ${ }^{\mathrm{b}}$ Survival rates are for hatchery eggs and hatchery fry plants and do not inlcude the lake incubators.
