## EXECUTIVE SUMMARY

Postseason final estimates of catches and escapements of Pacific salmon returning to the transboundary Stikine, Taku, and Alsek Rivers for 2004 were presented and compared with historical patterns. Average, unless stated differently, refers to the 1994-2003 averages. Relevant information pertaining to the management of appropriate U.S. and Canadian fisheries is presented and the use of inseason management models is discussed. Results from transboundary river sockeye salmon Oncorhynchus nerka enhancement projects are also reviewed.

## Stikine River

The 2004 Stikine River sockeye salmon run was estimated at 310,000 fish, of which approximately 211,000 fish were harvested in various fisheries including test fisheries. An estimated 99,000 Stikine River fish escaped to spawn, including 300 fish that migrated to the Tuya River block that were not harvested. The run and harvest were above average. The Tahltan Lake sockeye salmon escapement of 63,000 was above the upper bound of the goal range ( 18,000 to 30,000 fish. The estimated U.S. commercial catch of Stikine River sockeye salmon in Districts 106 and 108 was 112,000 fish and the Canadian inriver commercial, aboriginal, and excess salmon to spawning requirement (ESSR) fishery catches combined were 86,000 fish. The inriver test fishery harvested 1,300 sockeye salmon and there was no marine test fishery in 2004. The Stikine Management Model (SMM) predicted a run greater than the preseason forecast after week 30 . Weekly inseason model forecasts ranged from 160,000 to 308,000 sockeye salmon; the final inseason model prediction was 299,000 fish (both U.S. and Canada), with a total allowable catch (TAC) of 242,000 fish. Based on the postseason run size estimates and TAC calculations of 96,000 Stikine River fish for each country, Canada harvested $65 \%$ and the U.S. harvested $95 \%$ of their respective TACs. The broodstock collection and otolith sampling removed 4,200 and 400 sockeye salmon respectively from the escapement to Tahltan Lake leaving a spawning escapement of 58,700 fish. The estimated spawning escapement of 36,000 mainstem Stikine River sockeye salmon was within the goal of 20,000 to 40,000 fish for this stock group. The total sockeye salmon run calculated from mark-recapture study was 208,000 sockeye salmon, approximately $10 \%$ greater` than the estimate generated from the test fishery CPUE.

The harvest of Chinook salmon O.tshawytscha in Canadian commercial and aboriginal fisheries in the Stikine River was 3,900 large fish and 2,600 non large fish; both above average. An additional 50 large and 80 non large Chinook salmon were taken in the Canadian inriver test fishery. The U.S. marine harvest of Chinook salmon (all stocks) in the District 106 and 108 mixed stock gillnet fisheries of 10,100 fish was above average. The Chinook salmon spawning escapement of 16,400 large adults through the Little Tahltan River weir was twice the upper bound of the escapement goal range of 2,700 to 5,300 fish and the highest on record. The total Stikine River Chinook salmon escapement as estimated from a mark-recapture study was 49,000 fish.

As with Chinook salmon, the U.S. marine harvest of Stikine River coho salmon $O$. kisutch is unknown since there is no stock identification program for this species. Mixed stock coho harvests in Districts 106 and 108 were 136,400 and 26,400 fish, respectively; above average. Alaskan hatchery fish comprised approximately $36 \%$ and $9 \%$ of the harvest in Districts 106 and 108, respectively. The Canadian inriver coho catch of 300 fish was $25 \%$ of average. The aerial survey count from six index sites of 3,000 fish was $75 \%$ of average.

## Taku River

The postseason estimate of the 2004 Taku River sockeye salmon run was 204,015 fish, including an estimated catch of 98,000 fish and an above-border spawning escapement of 107,000 sockeye salmon. The run size was below average and the escapement was above the escapement goal range of 71,000 to 80,000 fish. An estimated 77,000 Taku River sockeye salmon were harvested in the District 111 commercial fishery; below average, and an estimated 1,000 sockeye salmon were harvested in the U.S. inriver personal use fishery. Canadian inriver commercial harvested 20,200 sockeye salmon and aboriginal fishery harvest 100 sockeye salmon. The commercial harvest was below average. In 2004, Canada harvested an estimated $16 \%$, and the U.S. harvested $60 \%$ of the TAC.

The harvest of large Chinook salmon in the Canadian commercial fishery in the Taku River was 2,100 fish; above average. In addition, 300 non large Chinook salmon were harvested; above average. The Canadian aboriginal fishery in the Taku River harvested 500 large Chinook salmon. District 111 mixed stock gillnet fishery harvest of 2,300 Chinook salmon was average. Approximately $21 \%$ of the harvest was estimated to be of Alaska hatchery origin. The escapement of 9,100 Chinook salmon counted in Taku River index areas was average, and was in the revised index escapement goal range of 5,800 to 10,500 fish. The above-border mark-recapture estimate for Chinook salmon is 78,000 fish.

The estimated above border run of Taku River coho salmon in 2004 was 144,000 fish, which was above average. The Canadian inriver commercial harvest included 6,000 coho salmon; average. After upriver Canadian harvest are subtracted from the inriver run, the above-border spawning escapement was estimated at 134,500 coho salmon, which exceeds the minimum escapement goal of 38,000 fish. The U.S. harvest of 45,300 coho salmon in the District 111 mixed stock fishery was 1average. Alaskan hatcheries contributed an estimated $6 \%$ of the District 111 harvest, or 2,600 fish.

The harvest of 150,400 pink salmon O. gorbuscha in District 111 was above average. Pink salmon were not retained in the Canadian commercial inriver fishery in 2004. The Taku River pink escapement was likely below above average, as evidenced by the fish wheel catch and release of 8,500 which was below average.

The catch of chum salmon $O$. keta in the District 111 fishery was 131,500 fish, and was composed of 126,000 summer run fish (prior to mid-August) and 5,400 fall run fish. The harvest of summer chum salmon, primarily Alaskan hatchery stocks, was below average.

The harvest of fall chum salmon, composed of wild Taku River and Port Snettisham stocks, was average. As with pink salmon, there was non-retention of chum salmon in the Canadian inriver fishery and the reported catch was 0 fish in 2004. Although spawning escapement is not known the Canyon Island fish wheel catch of 400 chum salmon was above average.

#### Abstract

Alsek River The Alsek River sockeye salmon harvest of 18,000 fish in the U.S. commercial fishery was average. The Canadian inriver harvest of 2,100 fish was above average harvest. The Klukshu River weir count of 15,400 sockeye salmon was average and just above the goal-range of 7,500 to 15,000 fish. The count of 3,500 early run sockeye salmon (count through August 15) was above average. The late run count of 11,900 fish was average. The mark-recapture program indicated an Alsek River sockeye salmon run above Dry Bay of 70,200 fish with the Klukshu stocks representing 22\% of the total Alsek River run.

The Chinook salmon run to the Alsek River appeared to be near average. The U.S. Dry Bay catch of 660 Chinook salmon was average. The combined Canadian sport and aboriginal fishery catch of 190 Chinook salmon was below average. The 2,500 Chinook salmon counted through the Klukshu River weir was average. Of the total count, 2,500 Chinook salmon were estimated to have spawned, over the goal range of 1,100 to 2,300 Chinook salmon. The mark-recapture estimate of the spawning escapement of large fish in the Alsek River was 7,565 large Chinook salmon (Appendix E. 11).

Current stock assessment programs prevent an accurate comparison of the Alsek River coho salmon run with historical runs. The U.S. Dry Bay catch of 2,550 coho salmon was below average, while the combined Canadian inriver aboriginal and sport fishery catch of 130 fish was average. The operation of the Klukshu weir does not provide a complete enumeration of coho salmon into this system since it was removed before the run was over; however, it does provide an annual index. The count of 7,500 coho salmon was below average.

## Enhancement

Eggs and milt were collected from the year 2004 sockeye salmon escapements at Tahltan and Tatsamenie Lakes. A total of 6.1 million eggs were collected at Tahltan Lake. At Tatsamenie Lake, 2.6 million eggs were collected for the hatchery.

Outplants of 2003 brood-year sockeye salmon fry in May and June 2004 included, 2.2 million fry into Tahltan Lake, 2.4 million fry into Tuya Lake, and 2.1 million fry into Tatsamenie Lake. Green-egg to planted-fry survivals were $84 \%, 90 \%$, and $87 \%$ for the Tahltan, Tuya and Tatsamenie outplants, respectively. Survival to emergence were above average.

The egg incubation and thermal-marking program was continued at Snettisham Hatchery in 2004. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Adult sockeye salmon otoliths were processed inseason by the ADF\&G otolith lab to estimate the weekly contribution of fish from US/Canada TBR fry planting programs to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Final contribution estimates of planted fish to Alaskan harvest were 42,900 planted Stikine River fish to District 106 and 108, (19\% of that catch) and 700 planted Taku River fish to District 111 ( $<1 \%$ of that harvest). Final estimates of contributions to Canadian fisheries included 23,700 planted fish to Stikine River fisheries ( $31 \%$ of that catch) and 300 planted fish to the Taku River fisheries ( $<1 \%$ of that catch).

## INTRODUCTION

This report presents the final estimates of the 2004 catch and escapement data for Pacific salmon runs to the transboundary Stikine, Taku, and Alsek Rivers and discusses management actions taken during the season. Catch and effort data for each river for both U.S. and Canadian fisheries are presented by management week (also called statistical week; statistical weeks for 2004 are listed on page ii, before table of contents). Spawning escapement data for most species are reported from weir counts or other escapement monitoring techniques. Joint enhancement activities on the Stikine and Taku Rivers are also summarized.

The Transboundary Technical Committee (TTC) met prior to the season to update joint management, stock assessment and enhancement plans and determine preseason forecasts and outlooks for run strengths and initial total allowable catch TAC estimates for the various species and rivers. The results of this meeting are summarized in: Pacific Salmon Commission Transboundary Technical Committee, 2004. Salmon Management and Enhancement Plans for the Stikine, Taku and Alsek Rivers, 2004.

Run reconstruction analyses are conducted on the sockeye salmon Oncorhynchus nerka runs to the three rivers for the purpose of evaluating the stocks and the fisheries managed for these stocks. No estimates of marine catch are made for Alaskan fisheries outside of District 106 and 108 for Stikine River stocks, District 111 for Taku River stocks and Subdistrict 182-30 and -31 for Alsek River stocks.

## STIKINE RIVER

Stikine River salmon are harvested by U.S. commercial gillnet fisheries in Alaskan Districts 106 and 108, by Canadian commercial gillnet fisheries located in the lower and upper Stikine River, and by a Canadian aboriginal fishery in the upper portion of the river (Figure 1). In addition, Canadian terminal area fisheries are operated in the lower Tuya River and/or at Tahltan Lake when escapements are estimated to include excess salmon to spawning requirements (ESSR). A small sport fishery also exists in the Canadian sections of the Stikine River drainage. In 1995, a United States personal use fishery was established in the lower Stikine River; no catches were reported in this fishery in 1995 through 2000, approximately 30 sockeye salmon were harvested in 2001, and the personal use fishery on the Stikine River was not open in 2002 and 2003. A subsistence fishery was opened in 2004. Additional catches of unknown quantity are taken in U.S. troll and seine fisheries and in sport fisheries near Wrangell and Petersburg. In 1996, the spring experimental troll area in the District 110 portion of Frederick Sound was expanded to target hatchery Chinook salmon (O. tshawytscha); four previous areas were combined into one large area that also included previously unopened waters. This area was the same in 2003. In 1993 the spring experimental troll fishery near Wrangell was expanded to include 2 new areas in portions of District 106 and 108 to target hatchery Chinook salmon. In 1998 an additional area was included in a portion of District 108. In 2002 this area was excluded and another small portion of District 108 was included in the experimental fishery. In 2003, the new area included in 2002 was excluded.

## Harvest Regulations and the Joint Management Model

Negotiations between Canada and the United States to replace expired portions of Annex IV, Chapter 1 of the Pacific Salmon Treaty resulted in the following arrangements for Stikine River salmon which are expected to be in place for the 1999 to 2008 period:

1. General:

The Parties shall improve procedures for coordinated or cooperative management of the fisheries on transboundary river stocks. To this end, the Parties affirm their intent to develop and implement abundance-based management regimes for transboundary Chinook salmon, sockeye salmon, and coho salmon (O. kisutch), no later than May 1, 2004.
2. Sockeye salmon:
(i) Assessment of the annual run of Stikine River sockeye salmon shall be made as follows:
a. a preseason forecast of the Stikine River sockeye salmon run will be made by the Committee prior to April 1 of each year. This forecast may be modified by the Committee prior to the opening of the fishing season;
b. inseason estimates of the Stikine River sockeye salmon run and the Total Allowable Catch (TAC) shall be made under the guidelines of an agreed Stikine Management Plan and using a forecast model developed by the Committee. Both U.S. and Canadian fishing patterns shall be based on current weekly estimates of the TAC. At the beginning of the season and up to an agreed date, the weekly estimates of the TAC shall be determined from the pre-season forecast of the run strength. After that date, the TAC shall be determined from the inseason forecast model;

Figure 1. The Stikine River and principal U.S. and Canadian fishing areas.
c. modifications to the Stikine Management Plan and forecast model may be made prior to June 1 of each year by agreement of both Parties. Failure to reach agreement in modifications shall result in use of the model and parameters used in the previous year; and,
d. estimates of the TAC may be adjusted inseason only by concurrence of both Parties' respective managers. Reasons for such adjustments must be provided to the Committee.
(ii) The Parties desire to maximize the harvest of planted Tahltan/Tuya sockeye salmon in their existing fisheries while considering the conservation needs of wild salmon runs. The Parties agree to manage the runs of Stikine River sockeye salmon to ensure that each country obtains $50 \%$ of the TAC in their existing fisheries. Canada will endeavor to harvest all fish surplus to escapement and broodstock needs returning to the Tuya and Tahltan Lake systems.
(iii) The Parties agree to continue the existing joint enhancement programs designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) Consistent with paragraph 1 above, the Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Stikine River. Assessment programs need to be further developed before a MSY escapement goal can be established.
(ii) In the interim, the United States’ management intent is to ensure that sufficient coho salmon enter the Canadian section of the Stikine River to meet the agreed spawning objective, plus an annual Canadian catch of 4,000 coho salmon in a directed coho salmon fishery.
(3) Chinook salmon:
(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Stikine River are achieved.
(ii) The Parties agree that new fisheries on Stikine River Chinook salmon will not be developed without the consent of both Parties. Consistent with paragraph 2, management of new directed fisheries will be abundancebased through an approach to be developed by the Committee. The Parties agree to implement assessment programs in support of the development of an abundance-based management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Stikine River Chinook salmon by May 1999 and establish a new goal as soon as practicable thereafter.

As in most previous years, the Transboundary Technical Committee (TTC) met prior to the season to update joint management and enhancement plans, develop run forecasts and determine new parameters for input into the inseason run forecast model, referred to as
the Stikine Management Model (SMM). The model was upgraded to provide inseason forecasts of the total Stikine River sockeye salmon run as well as the following components of the run: the Tahltan stock (wild and planted combined); the planted Tuya stock; and the mainstem stocks. The model for 2004 was based on catch per unit effort (CPUE) data from 1985 to 2003 from District 106 and the Canadian commercial fishery in the lower river and from 1986 to 2003 from the lower Stikine River test fishery. Linear regression was used to predict run size from cumulative CPUE for each (statistical) week of the fisheries, beginning in week 25 for District 106 and week 26 for the inriver fisheries. As in 1999 to 2003, the intercept was forced to be zero in order to correct for a tendency to overestimate the run size in the early weeks during years of low abundance. Each CPUE and run size data set is significantly correlated.

Initially in 2004 the inriver test fishery CPUE was the primary forecast used however, the CPUE from the commercial fishery was used after week 27 (extended fishery openings provided more data than the limited or absent test fishery). Calculations for the lower Stikine River commercial CPUE excluded catch and effort data from the Flood Glacier area, i.e., the new area introduced in 1997 and fished through the 2000 season and again opened in 2004. In addition, the annual weekly CPUE values for 1994 through 2000 were decreased by a factor of 0.75 for the extra gear allowed in the commercial fishery during that period. This made the historical CPUE data for that period more comparable with the 2004 fishing season and the pre-1994 era.

In 2004, the preseason forecasts were used during weeks 25 (June 20 to 26) through 26 (June 27 to July 03). A combination of preseason forecast and test fishery CPUE were used for week 27 (July 04 to July 10). After week 27, inseason forecasts of total run size and TAC, produced by the SMM and based on catch-per-unit-effort (CPUE) data, were used to assist in determining weekly fishing plans (Table 1). The weekly inputs to the model included: the catch, effort and stock composition (proportion Tahltan/Tuya from egg diameters, proportion planted Tuya from thermal mark analyses of otoliths) in the Canadian lower river test and commercial fisheries; the upper river catch in the aboriginal fishery (AF) and upper river commercial fishery; the catch, effort and assumed stock composition in Subdistrict 106-41 (Sumner Strait); and, the catch and assumed stock composition in District 108 and Subdistrict 106-30 (Clarence Strait). Preliminary results of thermal mark analyses were available inseason for the marine and lower river fisheries to account for Tuya production in the model and reduce the risk of over-estimating the TAC of Tahltan sockeye salmon.

Table 1. Weekly forecasts of run size and total allowable catch for Stikine River sockeye salmon as estimated inseason by the Stikine Management Model, 2004.

${ }^{\text {a }}$ does not include test fishery catches
Initially, average stock proportions in District 106 and 108 catches, from historical postseason scale pattern analysis (SPA), were assumed for weekly catches; the averages used each week depended upon whether the run was judged to be below average, average, or above average. The Tuya and planted Tahltan stock proportions were subsequently adjusted inseason based on the analysis of otolith samples taken in Districts 106 and 108. Inseason otolith sampling was conducted to estimate the contribution of planted Tahltan and Tuya Lake sockeye salmon to catches in these areas. The weekly estimate of Tuya fish in District 106-41 and -108 was added to the historical proportion of Tahltan fish in the SMM since this stock was not present in the historical database.

The preseason forecast for the Stikine River sockeye salmon run was approximately 233,000 fish (Table 1), which indicated a run size about 50,000 fish greater than the average run (Appendix B.28). The forecast included approximately 102,100 natural Tahltan sockeye salmon (44\%), 58,700 planted Tahltan fish (25\%), 27,500 planted Tuya sockeye salmon (11\%), and 44,400 mainstem fish (19\%). Canadian inseason predictions of total run ranged from 208,000 to 308,900 sockeye salmon; U.S. forecasts ranged from 160,000 to 298,7 sockeye salmon (Table 1). All forecasts indicated an above average run. Even though run size generated from the inriver test fishery data has proven more accurate than that generated from the commercial fishery data in past years, the limited duration of the test fishery forced use of the commercial fishery data 2004. Differences in
U.S. and Canadian weekly predictions are due only to different catch data inputs being used for the updates.

The final postseason estimates of run size and TAC are larger than those used inseason for management. The inseason forecast tended to underpredict the run during the peak weeks of the fishery, in part, due to evidently delayed migratory timing. The inseason forecasts increased throughout the duration of the run and by the end of the fishery were within 3000 fish of the postseason estimate (Table 1).

## U.S. Fisheries

The 2004 gillnet harvest in District 106 included 2,735 Chinook salmon, 116,259 sockeye salmon, 138,631 coho salmon, 245,237 pink salmon, and 110,574 chum salmon (Appendix A. 1 and B.1). The harvests of all salmon species except Chinook salmon were below average (Figure 2 Appendix B.1). The District 106 total harvest of Chinook salmon was the highest on record. The final postseason estimate of the contribution of Stikine River sockeye salmon to the District 106 total sockeye salmon harvest was 33,000 fish or $28.3 \%$ of the harvest (Appendix A. 2 and B.2). Second year returns of sockeye salmon to Neck Lake contributed an estimated 3,251 (2.8\%) to the District 106 fishery. An estimated 1,281 Chinook salmon in the District 106 harvest (46.8\%) were of Alaska hatchery origin (Appendix A.1). An estimated 49,500 coho salmon were of Alaska hatchery origin, $35.7 \%$ of the total coho salmon harvest. The District 106 drift gillnet fishery was open for 55 days from June 13 through October 5 (Appendix A. 1 and B.1). This was above average fishing time of 44.3 days. Sections $6-A, 6-B$, and $6-C$ were open simultaneously each week throughout the season. Fishing effort in number of vessels fishing in District 106 was below average for the most of the season (Appendix B.1). The greatest effort in vessels fishing, 83 boats, occurred in week 37 . However, the greatest effort in boat days (280) occurred near the beginning of the season in week 27 (Appendix A.1). The total season effort was 2,735 boat days, below average (Appendix B.1).

The Sumner Strait fishery (Subdistricts 106-41 and -42) harvested an estimated 31,000 Stikine River sockeye salmon (Appendix A. 4 and B.4), $36.1 \%$ of the total sockeye salmon harvest in that subdistrict. The Clarence Strait fishery (Subdistrict 106-30) harvested and estimated 2,000 Stikine River sockeye salmon (Appendix A. 6 and B.6), $6.5 \%$ of the total sockeye salmon harvest in that subdistrict.

In District 108, 7,410 Chinook salmon; 103,392 sockeye salmon, 26,617 coho salmon, 20,439 pink salmon, and 37,996 chum salmon were harvested for the season (Appendix A. 7 and B.7). The total harvest of Chinook salmon was the $4^{\text {th }}$ highest on record and the highest since 1974. Total sockeye harvest was above average. The District 108 fishery harvested an estimated 81,000 Stikine River sockeye salmon (Appendix A. 8 and B.8), $78.3 \%$ of the District 108 sockeye salmon harvest (Figure 3). District 108 started concurrently with the District 106 fishery on June 13th and ran through October 5. The 53 days the district was open was above average despite being closed for 2 consecutive weeks at the end of July (Appendix A. 7 and B.7). District 108 was open for at least three days a week with the exception of weeks 31 and 32 when it was closed due to concern for
the Stikine River mainstem sockeye run. An estimated 9.2\% of the coho salmon harvest (2,447 fish) was of Alaskan hatchery origin (Appendix A.7). The fishing effort in number of vessels fishing in District 108 was at or above average for most openings. The season effort of 1,824 boat-days in District 108 was above average boat-days (Appendix B.7).

The District 108 test fishery did not take place in 2004 (Appendix A.9). Annual harvests and stock compositions from 1960 to 2000 for District 6 and 8 test fisheries are provided in Appendices B.9-B.11.

The 2004 season was the first season a U.S. Federal subsistence fishery was conducted on the Stikine River. The fishery was managed by the United States Forest Service. A permit issued by the USFS to Federally qualified users was required. The fishery took place on the Stikine River upriver from marine waters to the U.S./Canadian border. Fishing in "clearwater" tributaries or side channels and at stock assessment sites was prohibited. A 600 sockeye salmon Guideline Harvest Level was in place. The open dates for the fishery were July 1 to July 31. The allowable fishing gear for the fishery was dipnets, spears, gaffs, rod and reel, beach seine, or gillnets not exceeding 15 fathoms in length with mesh size no larger than $51 / 2$ inches. A total of 40 permits were issued but only 20 actively fished. Of those 20 that fished, 15 landed a total of 243 sockeye.

Harvests in Districts 106 and 108 consist of species of mixed stock origin; the contribution of Stikine River stocks is estimated only for sockeye salmon. The proportions of Stikine River sockeye salmon in the District 106 and 108 harvest were estimated inseason using both the historical proportions of each stock and the inseason proportions of thermally marked fish from fry plants to Tahltan and Tuya Lakes.

The District 106 and 108 gillnet season began 12:00 noon on Sunday, June 13 (statistical week 25) for a 72 hour period. District 108 was open to the inner Stikine closure line from Point Rothsay to Indian Point and with a closure around the northern entrance to Wrangell Narrows. This opening is normally 2 days and any decision to extend fishing is based on fishery harvest rates estimated by management biologists on site in the fishery. However, an initial three days was given due to the large forecast of Talhtan sockeye salmon and a lack of conservation concern for Stikine Chinook salmon. The estimated sockeye salmon CPUE in both districts for statistical week 25 was below average for this week (Appendix A.2). However, the fishery was open in week 25 in only six years in District 106 and four years in District 108 during the 1994 to 2003 period. There were 16 boats fishing in Sumner Strait (106-41) and no boats were fishing in Clarence Strait (10630) during this opening. District 108 had an above average number of boats fishing with 31 boats making landings. (Appendices A. 3 and A.5). The inseason otolith readings for District 106 indicated that the harvest in Sumner Strait consisted of 7\% marked Tahltan bound fish) and only $1.9 \%$ of Tuya fish. The District 108 fishery had a higher proportion of marked Talhtan (16.7\%) and Tuya (3.6\%). The preseason SMM forecasted a total Stikine River TAC of 172,595 fish and a Tahltan TAC of 135,547 (Table 2). This would allow the U.S. fisheries to harvest a total of 86,297 Stikine River fish, including 67,774 Tahltan fish. The pre-season forecast was used for weeks 25 to 27, the inriver test fishery CPUE for week 28 and the lower river commercial fishery CPUE was used for the
remainder of the sockeye salmon season. Normally, the inriver test fishery CPUE data is used for the remainder of the season after week 27 but the test fishery was not conducted for 2 weeks ( 28 and 29) during the peak of the sockeye run when the lower river commercial fishery was open for seven days a week. The lower river commercial CPUE continued to be used after the test fishery started again because of reduced drifts in the test fishery and the consistency of the lower river commercial CPUE data.

During statistical week 26 (June 20 to June 26) there were 31 boats fishing in Sumner Strait, 2 boats fishing in Clarence Strait and 28 boats in District 8 for the initial 3 days (Appendices A. 3 and A.5). The sockeye salmon CPUE in both districts was well above average for this week. District 108 was open for an additional 2 day midweek opening. An additional 27 boats made landings in the midweek opening making a total of 55 boats fishing in the district for the week. However, there was no fishery extension in District 106.

During week 26 (June 22 to June 28) there were 36 boats fishing in Sumner Strait and 9 boats fishing in Clarence Strait (Appendices A. 3 and A.5). The sockeye salmon CPUE in District 106 was above the 1993 to 2002 average for this week however there was no fishery extension in District 106 and District 108 remained closed.

During week 27 (June 27 to July 3), there were 46 boats fishing in Sumner Strait, 10 boats fishing in Clarence Strait and 48 boats fishing in District 108 (Appendices A. 3 and A.5). Due to the uniformly very good sockeye catch rates indicated by the in-fishery survey in both districts a 2-day extension in both districts occurred bringing the total open time to 5 days. The District 106 sockeye salmon harvest and CPUE were substantially above the respective 1994 to 2003 averages. The District 108 CPUE was above average and the total harvest for the week was just below average. This week the SMM switched from the preseason forecast to a forecast based on the Canadian inriver test fishery CPUE for the week 28 projections (Table 1). The inseason otolith readings for sub-district 10641 for week 27 indicated that $19.4 \%$ and $5.2 \%$ of the catch was comprised of thermally marked Tahltan and Tuya fish, respectively. The District 108 reading indicated 34.1\% thermally marked Tahltan and $5.2 \%$ thermally marked Tuya. The estimated U.S. harvest by the end of this week was 25,519 Tahltan sockeye salmon, while the SMM projected a U.S. TAC of 37,313 Tahltan sockeye salmon.

During week 28 (July 4 to July 10) District 106 and 108 were opened for an initial three days (Appendix A.7). There were 67 boats fishing in District 106 (21 in Clarence Strait and 46 in Sumner Strait) and a total of 83 boats fishing in District 108 for the week (Appendices A.3, A.5, and A.7). Surveys on the fishing grounds showed that the CPUE for the three-day opening was above average in both districts. A 2-day midweek opening occurred in District 108. On average, the peak Tahltan abundance occurs in District 106 in week 27; however, the 2004 statistical weeks were earlier than average, therefore week 28 was similar to the week 29 historical averages when the majority of the Tahltan run has passed through the District 106 fishery. The estimated U.S. harvest of Tahltan sockeye salmon in District 108 was 34,875 fish and 20,563 in District 106 making a total U.S. harvest of Tahltan sockeye salmon of 55,438 fish through week 28. The TAC from
the SMM was 66,658 Tahltan sockeye salmon. While the SMM forecast of Talhtan sockeye run increased this week to near the pre-season forecast, the forecast of the mainstem run decreased significantly to below preseason forecast.

During week 29 (July 11 to July 17), 68 boats fished in District 106 and 61 fished in District 108 (Appendices A. 1 and A.7). Indices of inriver run strength of Talhtan sockeye continued to be good with high catch rates in the lower river commercial fishery. Both districts were open for an initial 3 days of fishing time. Fishing ground surveys showed that sockeye salmon CPUE for the three-day opening was uniformly good in District 106 and well above average in District 108. A one-day extension occurred in both Districts. The inseason otolith readings for week 29 indicated that the marked Tahltan and Tuya fish contributed $6.7 \%$ of the District 106 catch and $19.9 \%$ of the District 108 catch. The SMM run prediction continued to increase for Talhtan sockeye salmon and decrease for mainstem sockeye salmon. The estimated U.S. harvest of Tahltan sockeye salmon by the end of this week was 77,692 fish, with a U.S. TAC of 83,470 fish. The estimated U.S. harvest of mainstem sockeye salmon was 17,017 fish with a U.S. TAC of 0 fish. The mainstem run was estimated to be 28,604 sockeye salmon. It was believed that the SMM was under forecasting the mainstem run size due to the Tahltan sockeye run being stronger and later than normal. The test fishery was not run this week or last week because the lower river commercial fishery was open continuously for 7 days each week. An enlarged closure around Salmon Bay was implemented to increase sockeye escapement into that lake system.

During week 30 (July 18 to July 24), there were 70 boats fishing in District 106 and 49 boats fishing in District 108 (Appendices A. 1 and A.7). Both districts were open for an initial 3 days. The CPUE in both Districts 106 and 108 was below average. No midweek openings or fishery extensions occurred. The U.S. catch of Tahltan sockeye salmon was estimated at 80,483 fish with a TAC of 99,574 fish. The inseason otolith readings for week 30 indicated that the marked Tahltan and Tuya fish contributed to $2.4 \%$ of the District 106 catch and $10.2 \%$ of the District 108 catch. The SMM estimated a total U.S. mainstem sockeye catch of 21,933 fish, with a TAC of 0 fish. The mainstem sockeye run size estimate dropped to 19,633 fish. Catch rates in the lower river commercial fishery were still high, but the proportion of Tahltan/Tuya fish to mainstem fish still remained fairly high.

During -week 31 (July 25 to July 31), District 108 was closed and District 106 was open for 2 days. District 108 was closed and time in district 106 was reduced due to the concern for the mainstem stock. The Talhtan and Tuya stock should have been mostly through the district fisheries based on historical migratory timing information and the relatively low abundance of thermally marked Tahltan and Tuya fish in week 30. The continual declining SMM mainstem stock forecasts and the poor sockeye catch rates in the prior week indicated that the mainstem stock run was more than likely as low, if not lower than the preseason forecast. In addition, preliminary mark and recapture estimates indicated a low mainstem run. A total of 70 boats fished in District 106 for the opening. Sockeye catch rates were improved from the prior week and were average. The U.S. catch of Tahltan sockeye salmon was estimated at 81,054 fish with a TAC of 103,439
fish. The SMM estimated a total U.S. mainstem sockeye catch of 22,771 fish, with a TAC of 3,909 fish. The mainstem sockeye run size estimate nearly doubled this week to 38,161 fish.

During statistical week 32 (August 1 to August 7), District 106 was open for an initial 3 days and District 108 remained closed. A one-day extension occurred in District 106 due to the increased proportions of pink salmon in the catch. The final model run in week 32 indicated a total U.S. harvest of Stikine sockeye to be 111,468 with a total U.S. TAC of 120,726 (Table 1). The U.S. Tahltan sockeye harvest was estimated to be 81,580 fish with a U.S. TAC of 102,016 fish. The mainstem sockeye harvest by the U.S. was estimated to be 24,380 fish, with a TAC of 12,779 fish. The total sockeye run estimate increased to 55,901fish, approximately 11,500 fish above the preseason forecast.

During statistical weeks 33 through 35, both Districts 106 and 108 were managed for pink salmon. District 108 was re-opened in week 33. Both Districts were open four days a week during through week 35 . Section D of District 106 was closed from week 33 through statistical week 36 . Pink harvests in both districts are not always a true reflection of abundance because low prices for pink salmon and catches of other more valuable species may affect the fishing patterns and methods. During the 2004 season, the fishing effort was substantially less than average in most weeks. Total pink harvest was below average (Appendices B. 1 and B.7).

Coho salmon management typically commences in late August or early September in both the District 106 and 108 gillnet fisheries. During week 36 (August 29 to September 4) the management emphasis changed from pink salmon to coho salmon. Prior to the change to coho salmon management the District 106 fishery harvested 86,111 coho salmon, approximately $62 \%$ of the total District 106 coho catch. The Alaska coho hatchery contribution to the District 106 fishery was above average the first 5 weeks but below average the remainder of the season. Catch rates during the fall coho season were generally below average in both districts. Districts 106 and 108 were open three days per week from week 36 through 41, except in weeks 37 and 41 when the districts were only open for 2 days per week. (Appendices B. 1 and B.7). Troll coho catch rates across the region were very good. Abnormal weather patterns may have contributed to the poor gillnet catches. The season ended with a final 2-day opening during week 41 (October 3 to 9).

## Canadian Fisheries

Final harvest estimates from the combined Canadian commercial and aboriginal gillnet fisheries in the Stikine River in 2004 included: 3,857 large Chinook, 2,574 non large Chinook salmon, 84,866 sockeye salmon, 275 coho salmon, 8 pink salmon, and 133 chum salmon (Appendices A.10, A. 12 and A.13). In addition to these catches, 1,675 sockeye salmon were taken in a terminal fishery located at the mouth of the Tuya River (Table 2 and Appendix B.18). Catches of large and non large Chinook salmon, sockeye salmon, and chum salmon were above average. The catch of 3,857 large Chinook salmon was above average. The catch of 2,574 non large Chinook salmon was over above average (Appendix
B.17). The catch of 84,866 sockeye salmon was above average, while the catch of 133 chum salmon was average. The coho salmon and pink salmon catches of 275 and 8 fish respectively were below average. (Appendix B.17). The final estimate of the total contribution of sockeye salmon from the Canada/U.S. fry-planting program to the combined Canadian aboriginal and commercial fisheries was 26,689 fish, $31.4 \%$ of the catch (Table 2).

Two test fisheries (for sockeye salmon and coho salmon) were conducted for stock assessment purposes in the lower Stikine River in 2004. The test fisheries were located immediately upstream from the Canada/U.S. border. Combined test fishery catches included: 80 large Chinook, 51 non large Chinook salmon, 1,338 sockeye salmon, 487 coho salmon, 56 pink salmon, and 183 chum salmon (Appendix A.15). One objective of the sockeye salmon test fishery was to obtain data for a mark-recapture study. Additional objectives of the sockeye test fishery were similar to those in previous years: to provide inseason catch, stock ID and effort data for input into the SMM to forecast the inriver run size; and, to determine migratory timing and stock composition of the sockeye run for use in the postseason estimations of the inriver sockeye salmon and coho salmon run sizes. The objectives of the coho test fishery were to provide a measure of run timing through the fishery, age and gender profiles, and to assess relative run size based on catch per unit.

## Lower Stikine River Commercial Fishery

Canadian commercial fishers in the lower Stikine River harvested 2,431 large Chinook salmon, 2,077 non large Chinook salmon, 77,530 sockeye salmon, 271 coho salmon, 8 pink salmon, and 133 chum salmon in 2004 (Appendix A.10). The sockeye salmon catch was above average (Appendix B.12). The harvest of large and non large Chinook salmon was above average. The coho salmon and pink salmon catches of 217 and 8 fish, respectively, were below average. The chum salmon catch was above average.

Based on final estimates (Table 2), the stock composition of the lower river sockeye salmon catch was as follows: 21,894 planted Tahltan fish, $28.2 \%$ of the sockeye salmon catch; 34,319 wild Tahltan fish, $44.3 \%$ of the catch; 19,497 mainstem fish, $25.1 \%$ of the catch; and 1,819 planted Tuya fish, $2.3 \%$ of the catch (Appendix B.13).

Weekly guideline harvests, based on SMM forecasts of the total allowable catch (TAC) apportioned by average run timing and domestic and international allocation agreements, were developed each week to guide management decisions during the sockeye season. Particular attention was directed at the inriver run and escapement forecasts of the various stock groupings. Management through week 30 (week ending 24 July) was focused primarily on the Tahltan Lake sockeye stock, after which it switched to mainstem sockeye stocks through the end of August. Coho salmon management focus commenced at the end of August.

The fishery commenced at noon on Sunday, June 20 (week 26) for a scheduled opening of 2 days. The catches were below average partly due to high and rising water. The fishery was extended one day in an effort to make up for the poor fishing opportunities
during the first 2 days of the opening, in concert with expectations of seeing healthy sockeye numbers in the river based on both the preseason TAC and the above average catches in Districts 106 and 108 during week 25. Fishing effort was relatively light.

The fishery was posted for a three-day opening in week 27 (June 27 to July 03). CPUE in day one of the fishery was $50 \%$ below the average, but improved to approximately $76 \%$ of average in day 2. Tahltan/Tuya sockeye stocks (small-egg fish) represented over 90\% of the catch. The catch of Tuya fish was judged to be low based on the $6 \%$ showing of this stock in week 26. Tuya catches in 106 and 108 were also low in weeks 25 and 26. The above average catch and CPUE in District 108 during week 26, and the 2-day midweek extension, indicated a strong return and complemented the preseason forecast of an above average sockeye run. Canada's guideline catch for week 27 was approximately 15,000 fish; the catch totaled only 2,200 fish after 2 days of fishing. A SMM estimate based on the test fishery catches in week 26 indicated a Tahltan Lake sockeye run size of approximately 77,700 fish, less than half of the preseason expectation. The model estimate produced a Canadian guideline harvest of 8,000 fish for the current week, substantially less than the guideline harvest provided by the preseason forecast. The fishery was extended one day. No further extension were granted based on the uncertainty of the early season performance of the SMM and concerns that the model could potentially over-project run size as had occurred in past years. The cumulative catch of Tahltan Lake sockeye salmon for week 27 was 4,872 fish, well below the guideline catch of 8,000 to 15,000 fish. CPUE of Tuya Lake and mainstem sockeye stocks were well below average. It appeared that the fish were probably late entering the fishery, which may have been due to the above average water levels.

In week 28 (July 04 to July 10) the fishery was posted for a four-day initial opening with expectation of an extension, which was based on the record high test fish catches reported Friday through Saturday previous to the opening. The commercial fishery fishing zone was extend $\sim 25 \mathrm{~km}$ upriver to the mouth of Flood River. Daily CPUE effort was over double the average for the first three days of the fishery and the weekly guideline catch was $\sim 34,000$ Tahltan Lake sockeye salmon. This substantial increase of Canadian TAC was based on the assumption that the majority of Tahltan Lake fish ( $\sim 80 \%$ ) cleared the US fisheries and that the US could not catch their allocation. This observation prompted a 2-day extension. The catches of Tahltan Lake sockeye continued to be over twice the average for days four and five and represented $91 \%$ of the catch. The fishery was extended an additional day. The total catch of 22,000 Tahltan Lake sockeye salmon in the seven-day fishery prosecuted in week 28 was substantially below the target catch of approximately 34,000 fish. One licence fished for part of the opening at the newly opened upper zone of the fishery. The below average return of mainstem fish continued to hold over from week 27. The CPUE of Tuya Lake sockeye salmon was also below average.

The fishery was posted for four days for week 29 (July 11 to July 17), based on an inriver SMM projection of Tahltan lake sockeye salmon of $\sim 93,000$ fish, with a cumulative guideline harvest of $\sim 51,000$ Tahltan Lake fish. The guideline target for week 29 was ~24,000 Tahltan Lake sockeye salmon. The CPUE of Tahltan Lake sockeye stocks through to day three was almost double the average ( $205 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ vs. $115 \mathrm{~s} / \mathrm{f} / \mathrm{d}$ ). The total
catch after three days of fishing was $\sim 12,000$ fish. The abundance of Tahltan Lake sockeye salmon and the weekly guideline harvest after day three of the fishery prompted a four day extension. The total catch of Tahltan Lake sockeye salmon after day seven was 17,618 fish, well below the weekly guideline harvest of $\sim 24,000$ fish. The catch of Tuya sockeye salmon was well below average. The catch and CPUE of mainstem sockeye salmon was slightly above average, even though the management model indicate an inriver run size of $\sim 21,000$ fish, well below average, but within the escapement goal range of 20,000 to 40,000 fish. The upper fishing zone saw an increase in effort in week 29, with one licence fishing the entire opening and a second licence fishing approximately a third of the opening. The potential for an ESSR (excess to salmon spawning requirements) at Tahltan Lake was articulated to the Tahltan First Nations.

The fishery was posted for three days for week 30 (July 18 to July 24) based on a SMM projection of Tahltan lake sockeye stocks of $\sim 92,000$ fish, with a cumulative guideline harvest of $\sim 58,000$ Tahltan Lake fish. The allowable catch for week 30 was $\sim 13,000$ Tahltan Lake sockeye salmon. The overall CPUE observed in day one and 2 was close to three times average ( $220 \mathrm{sk} / \mathrm{net} / \mathrm{day}$ vs $77 \mathrm{sk} / \mathrm{net} / \mathrm{day}$ ). Tahltan Lake sockeye salmon were the predominate stock in the catch. The fishery was extended one day, based on the continued strong return of Tahltan Lake fish, and a projected Tahltan Lake weir count of $\sim 70,000$ sockeye salmon. The cumulative weir count on 21 July was 14,147 fish. The SMM continued to predict a weak return of mainstem fish, with an estimated inriver abundance of $\sim 21,000$ fish. An independent estimate using the historic mainstem sockeye CPUE against inriver run size was generated and indicated the inriver run size of mainstem sockeye salmon was $\sim 50,000$ fish, and, therefore, a Canadian TAC of $\sim 10,000$ fish. The cumulative catch of mainstem sockeye at the onset of week 30 was $\sim 6,400$ fish. The cumulative guideline catch for week 30 was $\sim 5,000$ fish ( $50 \%$ of the mainstem through by week 30), which was already exceeded before start of the week 30 fishery. The mainstem sockeye escapement projection was close to the low end of the 20,000 to 40,000 escapement goal range. The final week 30 catch of Tahltan Lake sockeye salmon was 6,649 fish with a cumulative catch of 51,293 fish. The total week 30 catch of mainstem sockeye salmon was 2,221 fish, with a cumulative catch of 8,606 fish. The catch of Tuya fish was 191, with a cumulative catch of 1,600 pieces. The Tahltan First Nations accepted the ESSR licence after researching the logistics and securing a market for the fish.

In week 31 (July 25 to July 31) the fishery was posted for four days. The CPUE of Tahltan Lake sockeye salmon of 52 fish/net/day was over double the average. The SMM model projected an inriver Tahltan run size of $\sim 143,000$ fish, while an independent regression analyses indicated an inriver run size of $\sim 129,000$ fish. Due to run timing of the Tahltan stock, whereby on average $96 \%$ of the fish transit the fishery by week 31, there was little chance in harvesting all of the $\sim 40,000$ surplus Tahltan fish. The SMM continued to predict a very weak return of mainstem sockeye. The inriver mainstem sockeye estimate was only 19,500 fish. An independent regression analyses indicated the run to be $\sim 51,000$ fish and thereby provided some mainstem sockeye stock TAC, based on attaining spawning numbers near the lower limit of the escapement range. The mainstem CPUE of 80 fish/net/day was above average of 69 fish/net/day. Primarily
because of the low mainstem sockeye return generated by SMM, the fishery was held at four days. The total catch for week 31 was 2,832 Tahltan Lake sockeye salmon, for a total cumulative catch of 54,125 fish. The catch of mainstem fish in week 31 was 4,346 fish for a total cumulative catch of 12,952 sockeye. US district 108 was closed in week 31. The Tahltan First Nations retired their ESSR licence, due to the low price offered for Tahltan Lake sockeye salmon. The ESSR licence was then open to other interested parties. Interest was expressed, but due to time constraints and the effort required to mount an ESSR fishery at Tahltan Lake, an ESSR fishery was not prosecuted.

In week 32, (Aug 01 to Aug 07) the fishery was posted for four days and extended an additional day based on the above average CPUE of mainstem fish ( 78 fish/net/day vs 46 fish/net/day) and on an increase in projected run size from both the SMM (22,900 fish) and the independent regression analyses (56,600 fish). The increase in mainstem sockeye catches and projections were likely due to the District 108 closure in week 31. District 108 was closed again in week 32. The final catch of Tahltan Lake sockeye in week 32 was 1,325 fish with a cumulative catch of 55,449 sockeye. The final catch of mainstem fish in week 32 was 4,799 fish with a cumulative catch of 17,752 sockeye.

In week 33, (Aug 08 to Aug 14) the fishery was posted for four days with no extensions granted. Very little fishing effort was expended in day four of the opening. The mainstem sockeye salmon CPUE of 54 fish/net/day was over double the average. Both the SMM ( 28,600 fish) and the independent regression analyses ( 62,500 fish) indicated an increase in run size of mainstem sockeye stocks. The latter estimate resulted in a weekly guideline catch of $\sim 11,600$ fish, but a catch of this magnitude in week 33 when on average $90 \%$ of the mainstem run has exited the fishery was highly unlikely. The final catch of Tahltan Lake sockeye salmon in week 33 was 534 fish, with a cumulative catch of 55,983 fish. The final catch of mainstem sockeye salmon in week 33 was 1,718 fish with a cumulative catch of 19,470 fish, below the weekly guideline catch of $\sim 30,000$ fish as calculated from the independent regression analyses. The coho catch was 168 fish and did not appear to play a role in instigating an increase in fishing effort.

${ }^{\text {a }}$ Escapement into terminal and spawning areas from traditional fisheries.
${ }^{\mathrm{b}}$ Catch allowed in terminal areas under the Excess Salmon to Spawning Requirement license.
${ }^{\text {c }}$ Fish returning to the Tuya system are not able to access the lake where they originated due to velocity barriers.
${ }^{d}$ The number of Tuya fish that should be passed through traditional fisheries in order to harvest the Tuya stock at the same rate as the Tahltan stock to ensure adequate spawning escapement for Tahltan fish.
${ }^{\mathrm{e}}$ Includes traditional, ESSR, and test fishery catches.
${ }^{\mathrm{f}}$ Does not include ESSR or test fishery catches.
${ }^{\mathrm{g}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than in the listed fisheries.

In week 34, (Aug 15 to Aug 21) the fishery was posted for four days with no extensions granted. Again this week, both the SMM (38,000 fish) and the independent regression analyses ( $67,100 \mathrm{fish}$ ) indicated an increase in run size of mainstem sockeye. Several licences did not fish in week 34 . The remaining licences fished very lightly in week 34 catching only 7 Tahltan Lake sockeye and 23 mainstem sockeye. The coho catch was only 11 fish.

In weeks 35 to 38 , (Aug 22 to Sept 18) the fishery was posted to remain open to 18 September in order to target on coho salmon. Fishing effort was very light. The catches for this segment of the fishery were 6 sockeye salmon and 29 coho salmon. The final day of fishing was 05 September.

In general, sockeye salmon entered the lower Stikine commercial fishing grounds later than normal, when compared to average. Peak run timing, however, was normal. The observation was based on sockeye salmon CPUE in the lower river commercial fishery. The 2004 Stikine River sockeye run peaked in week 28 ( 04 to 10 July); the Tahltan and Tuya stocks peaked in week 28 ( 04 to 10 July); and, the mainstem stock peaked in week 31(25 to 31 July) (Appendix A. 11 and A.16), one week later than the normal average run timing. The Tahltan and Tuya stocks have similar timing.

As in recent years, terminal fishing activities again focused on the lower Tuya River, to harvest surplus fish returning from the fry-planting program. A six-person crew gillnetted the mouth of the Tuya River from 17 July to 07 August, and harvested a total of 1,675 sockeye salmon (Appendix B.18). In general the fishing conditions were very good, aided by the installation of an instream deflection weir, which served to enhance fishing conditions during periods of high flow. The fishery was originally scheduled to operate until late August. However, because of fish marketing problems, the fishing activities ceased on 07 August. The estimated harvest rate, even with the truncated fishery, was approximately 53\%.

Out of 18 licences available for the lower river commercial fishery, 11 licenses were issued in 2004 with a maximum of 11 licenses being active in any one week (Appendix A.10). The total effort was 517 permit-days, above average permit-days (Appendix B.12). Gear was restricted to one drift or set gill net. During the third week of the fishery (week 28, 04 to 10 July), the commercial fishing zone was extended upstream, approximately 25 km upstream of the original upper boundary, located at the mouth of the Porcupine River, to the confluence of the Flood and Stikine rivers. This extension encompassed the fishing zone fished in 1997 to 2000.

## Upper Stikine River Commercial Fishery

A small commercial fishery has existed near Telegraph Creek on the upper Stikine River since 1975. A total of 494 sockeye salmon was caught, which was above average (Appendices A. 12 and B.14). One non large Chinook salmon was harvested which was below average. The fishing effort was below average, with one fisher fishing four to seven days per week. A total of 18 days was fished and the total effort was 18 permitdays. The average fishing time was 23 days, with an average effort of 36 permit-days.

Fishery openings were based on the Lower Stikine commercial fishery openings, but lagged one week. The first opening, however, was concurrent with the lower fishery opening.

## Aboriginal Fishery

The Stikine River aboriginal fishery, which is located near Telegraph Creek, harvested 1,426 large Chinook, 496 non large Chinook, and 6,862 sockeye salmon (Appendix A. 13 and B.15). The harvest of large Chinook, non large Chinook, and sockeye salmon was above average (Appendix B. 15). In general, the fish were up to 2 weeks late arriving to the fishing grounds, but the peak catch and CPUE, occurring during week 29 ( 11 to 17 July), followed the normal recent 10-year peak run timing period.

## Escapement

## Sockeye Salmon

A total of 63,373 sockeye salmon was counted through the Tahltan Lake weir in 2004; above average. The 2004 sockeye count was above the upper range of the escapement goal of 18,000 to 30,000 fish (Appendices A. 17 and B.22). An estimated 25,333 fish ( $40.0 \%$ ) originated from the fry-planting program, which is close to the $43.7 \%$ contribution of smolts observed in 2001, the principal cycle year contributing to the 2004 return (Appendix B. 24). The estimate of planted fish numbers in 2004 was based on the proportion of thermally marked otoliths from samples collected in the lower Stikine River commercial fishery. A total of 420 sockeye salmon were sacrificed at the weir for stock composition analysis. In addition, a total of 4,423 sockeye salmon was collected for brood stock, resulting in a spawning escapement of 58,710 sockeye salmon (Table 2).

The spawning escapements for the mainstem and the Tuya sockeye stock groups are estimated indirectly, by computing the ratio of Tahltan to the mainstem and Tuya components in the total inriver sockeye salmon run. Stock identification data are collected in the lower river commercial and test fisheries. The ratios of Tahltan:mainstem and Tahltan:Tuya are applied to the estimated inriver Tahltan run size, to develop an estimate of the total inriver sockeye salmon run. The escapements for Tuya and mainstem sockeye stocks are estimated by subtracting the stock-specific inriver catches from the respective inriver run estimates.

The 2004 escapement estimates are 39,287 mainstem and 1,463 Tuya sockeye salmon. The mainstem sockeye salmon stocks spawn in tributaries and lakes other than Tahltan Lake, and in the mainstem and side sloughs of the Stikine River. The mainstem sockeye spawning escapement estimate was above average, and was in the escapement goal range of 20,000 to 40,000 fish. Aerial survey results indicated a below-average escapement (Appendix B. 23). The Tuya River sockeye salmon are blocked by natural barriers, located near the mouth of river, from entering potential spawning grounds of the Tuya Lake. Sockeye are fished below these barriers in an ESSR (terminal) fishery. The 2004 Tuya ESSR (terminal) fishery harvested 1,625 sockeye salmon, representing a harvest rate of $53.4 \%$ (Appendix B.18). The fate of the remaining 1,463 Tuya fish was uncertain.

A research study funded under the Northern Fund of the PSC investigated the behaviour of Tuya River sockeye after these fish enter the Tuya River in 2004.

For the fifth consecutive year, a sockeye salmon mark-recapture program was conducted, to develop an alternate abundance-based management regime for Stikine River sockeye salmon. The final estimate of the total escapement using the Darroch estimate was 207,621 (SE=8,042) sockeye salmon (marked=1,999, recovered=700, catch=78,868), ranging from 191,858 to 223,384 fish. This estimate was above the postseason escapement estimate, and was above the escapement estimate generated from the final run of the SMM. The final sockeye stock-specific escapement estimates based on the mark-recapture study were 99,528 Tahltan fish, 1,976 Tuya fish, and 46,478 mainstem fish.

## Chinook Salmon

The 2004 Chinook escapement enumerated at the Little Tahltan weir was 16,381 large and 250 non large fish (Appendices A. 19 and B.25). The escapement of large Chinook salmon in the Little Tahltan River was above the upper limit of the escapement goal range ( 2,700 to 5,300 fish with a point goal of 3,300 fish). The count of non large Chinook salmon was above average. Aerial surveys of the Tahltan River and Beatty Creek were discontinued in 2002. The peak survey Chinook count at Andrew Creek was 1,534 fish, well above average and slightly above the escapement goal range of 650 to 1,500 fish (Appendix B. 26). The aerial survey Chinook count for the Little Tahltan River was 6,014 fish, $36 \%$ of the weir count and above average.

A mark-recapture study was conducted in 2004 concurrent with the SCMM to assess the inriver Chinook salmon abundance. Inseason mark-capture estimates were calculated weekly post week 23 (30-May to 05-July). The final postseason estimate of total systemwide spawning escapement, based on tag recoveries in the commercial fishery and spawning ground recoveries was 48,900 large Chinook salmon. The escapement was above the escapement goal range of 14,000 to 28,000 fish. The escapement to the Little Tahltan River represented approximately $34 \%$ of the total Stikine River escapement, above average.

## Coho Salmon

Aerial surveys of eight index sites were conducted on 03 November. The results, under only fair viewing conditions, indicated the coho escapement to be below average. Note: extremely poor viewing conditions at the Craig River index site. The Craig River is believed to be a major Stikine River coho spawning site.

Too little data exist to estimate the escapement of coho salmon the Stikine River. DFO used test fishery coho and sockeye CPUE to estimate coho salmon-a coho test fishery was conducted from the 07 Sept to 14 October. Utilizing a standard drift gillnet ( 33 metre by 30 mesh by 9 cm mesh size) fishing a specific site, the test fishery cumulative weekly CPUE was 5.83 coho salmon, above average. The coho CPUE was $25.9 \%$ of the cumulative weekly sockeye salmon CPUE of 22.52. Based on the estimated inriver run size of sockeye salmon of 192,021 fish, and assuming the catchability of coho was the
similar to that of sockeye (the same fishing site and gear were used), the coho salmon escapement was approximately $49,051(192,021 * 0.259$ minus the inriver catch of 682). This estimate was above the upper limits of the 20,000 to 40,000 escapement goal range.

## Sockeye Salmon Run Reconstruction

The final postseason estimate of the terminal Stikine River sockeye salmon run size was 302,151 which 217,051 are of Tahltan Lake origin (wild \& planted), 8,183 are of Tuya origin (fry from Tahltan broodstock planted into Tuya Lake), and 85,100 are mainstem stocks (Table 2). These estimates are based on inseason and historical data including otolith recovery and analysis in the U.S. Districts 106 and 108 catches; otolith analysis, egg-diameter stock-composition based on scale pattern analysis, estimates for inriver catches from the Canadian commercial, aboriginal, ESSR, and test fishery catches; and escapement data. The 2004 total run was above average (Appendix B. 29) and slightly above the preseason forecast (Table 1).

## TAKU RIVER

Taku River salmon are harvested in the U.S. gillnet fishery in the Alaskan District 111, in northern Southeast Alaska seine and troll fisheries, and in the Juneau area sport fishery and inriver personal use fishery (Figure 6). Canadian fisheries for Taku River salmon include a commercial gillnet fishery located in the river near the Canada/U.S. border, an aboriginal fishery, and a sport fishery.

## Harvest Regulations

New fishing arrangements were in place in 1999 as a result of negotiations between Canada and the United States of Annex IV, Chapter 1 of the Pacific Salmon Treaty. The arrangements that are expected to apply to the Taku River for the 1999 to 2008 period are as follows:
(1) Sockeye salmon:
(i) Except as noted below, Canada shall harvest no more than $18 \%$ of the TAC of the wild sockeye salmon originating in the Canadian portion of the Taku River each year;
(ii) If the projected inriver escapement is greater than 100,000 sockeye salmon, Canada may, in addition, harvest $20 \%$ of the projected inriver escapement above 100,000 sockeye salmon;
(iii) The Parties agree to manage the runs of Taku River sockeye salmon to ensure that each country obtains catches in their existing fisheries equivalent to each country's share of wild sockeye salmon and a $50 \%$ share of fish originating from Taku River fry plants;
(iv) The Parties agree to continue the existing joint Taku River enhancement program designed to produce annually 100,000 returning sockeye salmon.
(2) Coho salmon:
(i) The Parties agree to develop and implement an abundance-based approach to managing coho salmon on the Taku River no later than May 1, 2004. The Parties commit to developing a revised MSY escapement goal to be implemented no later than May 1, 2004.
(ii) Until a new abundance-based approach is developed, the management intent of the United States is to ensure a minimum above-border inriver run of 38,000 coho salmon, and the following arrangements will apply:
a. no numerical limit on the Taku River coho salmon catch will apply in Canada during the directed sockeye salmon fishery (through statistical week 33);
b. if inseason projections of above-border run size are less than 50,000 coho salmon, a directed Canadian harvest of up to 3,000 coho salmon is allowed for assessment purposes as part of the joint Canada/US Taku River mark-recapture program;
c. if inseason projections of above-border run size exceed 50,000 coho salmon, a directed Canadian harvest of 5,000 coho salmon is allowed;
d. if inseason projections of above-border run size exceed 60,000 coho salmon, a directed Canadian harvest of 7,500 coho salmon is allowed;
e. if inseason projections of above border run size exceed 75,000 coho salmon, a directed Canadian harvest of 10,000 coho salmon is allowed.

Figure 2. The Taku River and principal U.S. and Canadian fishing areas.
(3) Chinook salmon:
(i) Both Parties shall take the appropriate management action to ensure that the necessary escapement goals for Chinook salmon bound for the Canadian portions of the Taku River are achieved.
(ii) The Parties agree that new fisheries on Taku River Chinook salmon will not be developed without the consent of both Parties. Management of new directed fisheries will be abundance-based through an approach to be developed by the Committee no later than May 01, 2004. The Parties agree to implement assessment programs in support of the development of an abundance-based management regime.
(iii) The Parties shall review an appropriate MSY escapement goal for Taku River Chinook salmon by May 1999 and thereafter establish a new goal as soon as practicable.

## U.S. Fisheries

The traditional District 111 commercial drift gillnet salmon fishery was open for a total of 63 days from June 20 through October 14, 2004 (Appendix C.1). The harvest totaled 2,291 Chinook salmon, 241,219 sockeye salmon, 45,294 coho salmon, 150,407 pink salmon, and 131,486 chum salmon. Harvests of Chinook and chum salmon were below average (Appendix D.1). The coho salmon harvest was average, and the harvest of sockeye salmon and pink salmon were above average. Weekly commercial fishery harvests and stock composition estimates for these fisheries are provided in Appendices C.1-C. 3 and annual harvests from 1960 through 2004 are provided in Appendices D.1D.3.

Hatchery stocks contributed significantly to the numbers of both sockeye and chum salmon harvested and minor numbers to the harvest of other species. The 2004 season was the fifth year of significant numbers of adult sockeye salmon returning to the Snettisham Hatchery inside Port Snettisham. These fish contributed significantly to the harvests primarily in Stephens Passage and to the Speel Arm Terminal Harvest Area (THA) fishery inside Port Snettisham.

The Chinook salmon harvest of 2,291 fish was below average (Appendix C. 1 and D.1). Alaskan hatchery Chinook salmon contributed 330 fish as estimated by coded wire tag (CWT) analysis, for approximately $14 \%$ of the harvest. The Taku River stock assessment program at Canyon Island provided data to estimate the above-border Chinook salmon run. This data with the spawning ground mark-recapture data was used to estimate the spawning escapement of 75,032 large Chinook salmon, above the upper bound of the 30,000-55,000 fish range.

The traditional District 111 sockeye salmon harvest was 241,219 fish; above average (Appendices C. 1 and D.1). Weekly sockeye salmon harvests in District 111 were below average in weeks 26 to 31 and weeks 40 to 41 . Weekly sockeye salmon harvests were above average during weeks 32 to 39 . Weekly sockeye salmon catch-per-unit-effort
(CPUE) was above average in eleven of the seventeen statistical weeks, and was 10 -year records for weeks 32 to 35 . Domestic hatchery sockeye salmon stocks started to contribute to the traditional fishery in weeks 28 and added significant numbers to the harvests in weeks 29 through 35. Fishermen targeting these runs of hatchery sockeye salmon and the Limestone Inlet hatchery chum salmon, increased the amount and percentage of fishing effort that occurred in Stephens Passage. Of the total traditional District 111 sockeye salmon harvest, $41 \%$ occurred in Stephens Passage, more than double the average. The contributions of wild Taku River and Port Snettisham sockeye salmon to the traditional District 111 harvest was not known until postseason analyses of stock identification data were available. However, the catch of thermally marked sockeye salmon from fry plants was estimated inseason from analysis of otoliths. Sockeye salmon from a joint U.S./Canada fry-planting program at Tatsamenie Lake contributed an estimated 676 fish to the fishery ( $0.3 \%$ of the harvest (Appendices C. 3 and D.2). Contributions of U.S. hatchery sockeye salmon to the traditional District 111 drift gillnet fishery totaled 151,141 fish or $63 \%$ of the harvest. These were predominately Port Snettisham hatchery sockeye salmon but also included a small number of thermally marked fish from a fry-planting program at Sweetheart Lake in Port Snettisham. Historical stock composition estimates were applied to the remainder of the harvest to estimate contributions of Taku River and Port Snettisham wild stocks to the weekly harvests. The final estimate of stock composition of the harvest of wild sockeye salmon in the traditional district was 75,142 (42\%) Taku River fish, and 9,153 (5\%) wild Port Snettisham fish (Appendices C. 2 and C.3). An additional 92,756 sockeye salmon were harvested in the Speel Arm THA fishery inside Port Snettisham. The majority of these fish were from hatchery releases, but a small portion of wild Speel Lake sockeye salmon stocks were also taken in this fishery. Stock composition estimates were based on combined postseason analysis of otoliths, scale pattern, and brain parasite incidence characteristics.

The traditional District 111 chum salmon harvest of 131,486 fish was below average (Appendices C. 1 and D.1). The summer chum salmon harvest of 126,064 fish comprised $96 \%$ of the season's chum salmon harvest. The summer chum salmon run is considered to last through mid-August (week 33) and was comprised mostly of domestic hatchery fish, with small numbers of wild fish contributing to the harvest. Chum salmon returns to DIPAC hatcheries in Gastineau Channel and to the DIPAC remote release site at Limestone Inlet contributed a major portion of the harvest but quantitative contribution estimates were not available. Approximately $44 \%$ of the total traditional District 111 chum salmon harvest was made in Taku Inlet, 54\% in Stephens Passage, and 2\% inside Port Snettisham. The harvest of 5,423 fall chum salmon, weeks 34 and later, was average (Appendix D.1). Most of these chum salmon are assumed to be wild fish of Taku and Whiting Rivers origin.

The District 111 pink harvest of 150,407 fish was above average (Appendices C. 1 and D.1).

Coho salmon stocks harvested in District 111 include runs to the Taku River, Port Snettisham, Stephens Passage, and local Juneau area streams as well as Alaskan
hatcheries. The traditional District 111 coho salmon harvest of 45,294 fish was average (Appendices C. 1 and D.1). Weekly coho salmon harvests were above average during weeks 31,36 , and 38 to 39 , but below average during the remainder of the season. Coho salmon CPUE was above average during weeks 29 to 31, 36, and 38 to 39. Alaskan hatchery coho salmon contributed 2,584 fish or $6 \%$ of the traditional District 111 harvest. For most of the season, weekly estimates of Taku River coho salmon abundance indicated an above average run size.

For the 2004 season, drift gillnet fishing time in the traditional District 111 areas was above average (Appendix D.1). The maximum number of boats participating in the fishery in a given week was 122 boats during weeks 33 (Appendix C.1). Fishing effort as measured by the total number of boats delivering fish each week times the number of days open to fishing was 3,442 boat-days for the season; average (Appendix D.1).

Management actions to conduct the Taku River drift gillnet fishery were limited to imposing restrictions in time and area. Because there is no bi-laterally agreed forecast for Taku River sockeye salmon, early season management of the District 111 fishery is based on fishery CPUE and Canyon Island fish wheel catches. As the fishing season progresses sufficient data is acquired to estimate the inriver run size from the mark-recapture program at Canyon Island and to use that estimate in conjunction with migratory timing and historical fishery harvest data to forecast the entire Taku sockeye run. In the first week of the season (week 26), which began June 20, three days of fishing time were allowed in both Taku Inlet (Subdistrict 111-32) and Stephens Passage (Subdistrict 11131). The traditional District 111 sockeye harvest in the first week was below average. Fishing time for week 27 was set for four days. By the fourth day of the fishery, the projected inriver sockeye run was estimated to be 19,900 fish (Table 3). Both Taku Inlet and Stephens Passage were opened for four days in week 28 (average). The traditional District 111 sockeye harvest for the week was below average. Approximately $78 \%$ of the sockeye salmon harvested during the week came from Taku Inlet, while the remainder was harvested in Stephens Passage. Both Taku Inlet and Stephens Passage were open for three days during week 29 due to below average harvest and CPUE. The traditional District 111 harvest of 17,197 sockeye salmon was below average with $79 \%$ of the harvest occurring in Taku Inlet.

During week 30, Taku Inlet north of the latitude of Circle Point was open for 2 days in accordance with the TBR agreement to conserve the expected weak Tatsamenie sockeye return. Stephens Passage was opened for three days, one day less than average due to the below average inriver sockeye estimate. The traditional District 111 sockeye harvest was below average, with 43\% of the harvest taken in Taku Inlet. Analysis of otoliths revealed that $52 \%$ (116 of 222) of the samples processed from Stephens Passage during this week were Snettisham hatchery sockeye salmon.

During week 31, Taku Inlet north of the latitude of Circle Point was open for 2 days in accordance with the TBR agreement, and Stephens Passage was open for four days. The traditional District 111 sockeye harvest of 24,198 fish was average for the week, with $23 \%$ of the harvest in Taku Inlet. Analysis of sockeye otoliths revealed that 76\% (296 of
390) of the samples processed from Stephens Passage during this week were Snettisham hatchery fish. The traditional District 111 coho harvest was 3,212 fish for the week (Appendix C.1); above average.

During week 32, Taku Inlet north of the latitude of Circle Point was open for 2 days in accordance with the TBR agreement, and Stephens Passage was open for four days. With encouraging escapement through Speel Lake weir, and masses of fish observed at the head of Speel Arm, the entrance to Port Snettisham (Subdistrict 111-34) was opened for four days. Section 11C (Subdistrict 111-20) was opened for four days in conjunction with Stephens Passage due to adequate pink salmon escapement in the area. The record weekly traditional District 111 drift gillnet sockeye harvest of 54,594 fish was over three times the average, with $86 \%$ ( 47,196 fish) harvested in Stephens Passage and Port Snettisham where the fleet was targeting hatchery sockeye salmon bound for Port Snettisham. Analysis of sockeye otoliths revealed that $81 \%$ (268 of 331) of the samples processed from Stephens Passage during this week were Snettisham hatchery fish.

The week 33 traditional District 111 drift gillnet harvest of 67,654 sockeye salmon was the second highest sockeye harvest for any statistical week since 1960, and over ten times the week 33 average of 6,610 fish. Taku Inlet north of the latitude of Circle Point was open for an average of three days, due to average fish wheel catches, and Stephens Passage including Port Snettisham and Section 11C, was open for 4 days. The Speel Arm THA (Subdistrict 111-33) was initially opened for four days due to good escapement through the Speel Lake weir, and then extended till further notice when the minimum escapement of 4,000 sockeye salmon to Speel Lake was accounted for. In the traditional District 111 fishing areas, 33\% of the 6,370 sockeye salmon harvested in Taku Inlet, 81\% of the 26,472 sockeye salmon harvested in Stephen's Passage, and $94 \%$ of the 34,812 sockeye salmon harvested inside Port Snettisham were of Port Snettisham hatchery origin. An additional 22,093 sockeye salmon were harvested in the Speel Arm THA in week 33.

The fall drift gillnet season in District 111 lasted nine weeks, beginning on August 15 in week 34, and lasting until October 14 in week 42. In the first week of the fall season (week 34), fishing time was set at four days in all the traditional drift gillnet areas to allow harvest of the strong Taku River coho return and continued harvest of Port Snettisham hatchery sockeye salmon. The week 34 traditional District 111 coho harvest of 3,113 fish was below average of 4,354 fish. Section 11C closed for the season at the end of the week 34 fishery. Taku Inlet openings were limited to three days per week in week 35, and 36 to conserve Taku River fall chum stocks, and Stephens Passage and Port Snettisham were open for an average of three days. The traditional District 111 coho harvest of 4,935 fish in week 35 was average, and the week 36 harvest of 8,160 fish was above average. During week 37, both Taku Inlet and Stephens Passage were initially opened for three days. As the opening progressed, Canyon Island fish wheel counts and inriver abundance estimates of coho salmon strengthened, prompting a one-day extension. Stormy weather hampered the fleet during week 37, and the traditional District 111 harvest of 3,780 coho salmon was well below average. The week 37 traditional District 111 harvest of 1,101 chum salmon however, was above average. Week 38 was
the last week open to drift gillnetting in Port Snettisham, and Taku Inlet, Stephens Passage, and Port Snettisham were open for four days. The week 38 traditional District 111 harvest of 10,901 coho salmon was above average, and the harvest of 1,175 chum salmon was above average. Taku Inlet and Stephens Passage were open four days per week during weeks 39 to 42 , closing for the season on October 14. The week 39 coho harvest of 4,030 fish was average, and the chum harvest was well below average. Effort dropped dramatically during weeks 40 and 41 , and there were no reported landings in week 42.

Table 3. U.S. inseason forecasts of terminal run size, TAC, inriver run size, and the U.S. harvest of Taku River sockeye salmon for 2004.

| Stat | Inriver <br> Run | Terminal <br> Run | Total | U.S. | Projected |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Week | 77,725 | 128,212 | 53,212 | 43,634 | 55,488 |
| 27 | 79,961 | 145,052 | 70,052 | 56,684 | 65,091 |
| 28 | 119,743 | 193,866 | 118,866 | 97,360 | 74,123 |
| 29 | 114,124 | 187,660 | 112,660 | 92,001 | 73,536 |
| 30 | 125,674 | 191,723 | 116,723 | 95,119 | 66,050 |
| 31 | 127,047 | 204,015 | 129,015 | 105,031 | 76,968 |
| Postseason |  |  |  |  | TAC |

Terminal run does not include any marine harvest of Taku River salmon that might occur outside of District 111.

Several other fisheries in the Juneau area harvested transboundary Taku River salmon stocks in 2004. Personal use permits were used to harvest an estimated 1,031 Taku River sockeye salmon (Appendix D.4). In 2004, an estimated 14,443 Chinook salmon were harvested by sport fisheries in the Juneau area. A number of stocks are known to contribute to the Juneau area sport fishery, including those from the Taku, Chilkat, and King Salmon rivers, as well as local hatchery stocks. The major contributor is large, wild mature fish from the Taku River through mid-May and Alaska hatchery fish thereafter. Of the Chinook salmon harvested 2,700 were estimated to be of Taku River origin, based on coded wire tag analysis and maturity data. The July Hawk Inlet shoreline purse seine fishery in Chatham Strait opened for 10 hours in week 28 and for two 15-hour openings in week 29. The first 2 openings had Point Marsden as the southern boundary, and the third opening had Point Hepburn as the southern boundary. All three openings had the latitude of Point Couverden as the northern boundary. The harvests for these fisheries totaled 536 Chinook salmon, 17,490 sockeye salmon, 3,799 coho salmon, 625,243 pink salmon, and 173,633 chum salmon. A large number of stocks, including those from the Taku River, contribute to this pink salmon-directed fishery. A purse seine test fishery was also conducted each week in weeks 27 through 30, between Hawk Inlet and Point Retreat, with harvests totaling 33 Chinook salmon, 1,731 sockeye salmon, 155 coho salmon, 16,152 pink salmon, and 8,903 chum salmon.

## Canadian Fisheries

Taku River commercial fishers harvested 19,860 sockeye, 5,954 coho, 2,082 large Chinook, and 334 non large Chinook salmon in 2004 (Appendix C.4). The sockeye catch was below average (Figure 8). Fish originating from fry plants contributed an estimated 265 fish to the catch, comprising $1 \%$ of the total sockeye harvest. The catch of coho
salmon was average. The catch of large and non large Chinook salmon was above average (Appendix D.5). There were 40 days of fishing; this was below average. The seasonal fishing effort of 294 boat-days was below average. As in recent years, both set and drift gill netting techniques were used with the majority of the catch taken in drift gillnets. Mesh sizes were restricted to less than 150 mm through July 16, to minimize the incidental catch of Chinook salmon. In the aboriginal fishery, 277 large and 116 non large Chinook salmon, 120 sockeye salmon, and 450 coho salmon were harvested.

The final inseason abundance estimate for the inriver coho run was 143,970 fish. Accordingly, as per PST provisions, the Canadian allowable catch after week 33 was 10,000 salmon. Only about $60 \%$ of this allocation was taken, since commercial fishing activity deceased significantly after week 34 . (A very small number of coho salmon would also have been harvested in the sport fishery; however, recreational catch figures are not currently available).

According to the final postseason run estimate of 201,636 wild sockeye salmon, Canadian catches (excluding test fishery catches) represented $15 \%$ to $19 \%$ of the TAC. The enhanced run size was estimated to be only 2,381 fish, 268 of which were harvested in Canadian commercial or aboriginal fisheries. This represented approximately 11.1\% of the Canadian TAC of enhanced fish.

Two test fisheries were conducted were conducted in 2004 to capture Chinook and coho salmon for stock assessment purposes. The Chinook test fishery took place from May 2 through June 15 (statistical weeks 19 to 25) and landed 1,489 large (greater than or equal to 660 mm mid-eye-to-fork length) Chinook salmon, 294 non large Chinook salmon, and 19 sockeye salmon. The coho test fishery took place from August 29 through October 9 (statistical weeks 36 to 41), and landed 3,266 coho salmon and 72 sockeye salmon.

The Canadian preseason sockeye forecast was for a total run of approximately 231,000 fish, which was the average of a sibling-based forecast ( 263,036 sockeye salmon) and a stock recruitment-based forecast (199,270 sockeye salmon). The sockeye forecast was below average run (Canadian estimate). The total run incorporates an assumed U.S. harvest of $5 \%$ in marine approach waters (outside District 111); the terminal sockeye run forecast was therefore approximately 219,000 fish. The preseason forecast was used to guide weekly management actions for the first 2 weeks of the season; thereafter, inseason forecasts based on the joint Canada/U.S mark-recapture project were used (Table 4). For coho salmon, the preseason outlook was for an above-average run, due to favourable smolt numbers encountered in the 2003 coded-wire tagging program.

Table 4. Canadian inseason forecasts of total run size, total allowable catch (TAC), and spawning escapement of Taku sockeye salmon, 2004.

| Stat. <br> Week | Total Run | TAC | Projected <br> Escapement | Canadian <br> TAC | Inseason <br> Guideline | Actual <br> Catch |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| 25 | 231,153 | 156,153 | 75,000 | 28,108 | 1,903 | 0 |
| 26 | 231,153 | 156,153 | 97,826 | 28,108 | 3,996 | 2,015 |
| 27 | 231,154 | 156,154 | 58,492 | 28,108 | 6,961 | 3,860 |
| 28 | 140,324 | 65,324 | 77,092 | 11,758 | 4,275 | 5,465 |
| 29 | 172,900 | 97,900 | 91,875 | 17,622 | 8,503 | 8,629 |
| 30 | 197,581 | 122,581 | 100,386 | 22,142 | 13,420 | 12,138 |
| 31 | 199,959 | 124,959 | 99,500 | 22,493 | 16,087 | 14,999 |

| 33 | 209,600 | 134,600 | 105,653 | 25,359 | 22,779 | 18,390 |
| 34 | 210,189 | 135,189 | 101,228 | 24,580 | 23,181 | 19,185 |
| 35 | 210,284 | 135,284 | 102,264 | 24,804 | 24,116 | 19,777 |
| 36 | 210,728 | 135,728 | 102,964 | 25,024 | 24,655 | 19,860 |

As in previous years, cumulative guideline harvests were developed each week to guide weekly management decisions so that: a) the catch was consistent with conservation and Treaty goals; and b) management was responsive to changes in forecasts of abundance, i.e. abundance-based. The guidelines were based on current inseason forecasts of the Canadian sockeye TAC (based on mark-recapture estimates) apportioned by historical run timing.

The commercial fishery commenced on June 20 (statistical week 26) for a scheduled opening of three days. An opening of three days was chosen over the more traditional 2 days for the following reasons:

- The Chinook run projection based on mark-recapture data was 44,000 fish assuming average timing. Test fishery CPUE was $20 \%$ above average despite high water levels. A high pressure weather system was in place indicating that water levels would be increasing. By-catch was not anticipated to interfere with reaching the escapement goal.
- Although total sockeye run forecast was only average, the parent-year escapements for Kuthai were much higher than last year's, which saw an aboveaverage escapement to the lake. In addition, although the cumulative fishwheel catch was average, the catches for the 2 days prior to the posting date (June 18) were 2.0 and 2.4 times average respectively. Furthermore, the opening was somewhat later than usual (week 26 as opposed to week 25).

A one-day extension was granted due to continued high fishwheel catches, and relatively low fishery catches believed to be partly due to high water levels.

The following week (i.e. week 27, starting June 27), was opened on four days. The guideline sockeye harvest based on the preseason forecast through this week was 6,961 fish, of which 2,015 had been taken in week 26, leaving a balance of 4,496 fish. Just prior
to the opening, the Tulsequah flood occurred in conjunction with what were already high water levels. The flood receded over days 1 and 2 but water levels still remained very high. An extension of one day was granted at the close of day 3 , since there were still 1,086 fish to be taken. Catch was anticipated to be low as water levels were rising again. The final sockeye catch for the opening was 1,845 fish.

The week 28 fishery opened on three days starting July 4. No extension was granted as both the preseason and inseason forecasts indicated that the guideline harvest had been exceeded. The final catch for the opening was 1,605 sockeye salmon.

Week 29 (starting July 11) also opened on three days. Based on inseason mark-recapture data the sockeye run projection was only 128,447 fish and the cumulative guideline harvest had been exceeded by 823 fish. However, it was anticipated that the run status would improve as the Trapper Lake stock moved in. This proved to be correct, with the projection increasing to 196,668 fish by the close of day 2 . The guideline harvest increased to 12,335 fish, versus an actual catch of 7,672 fish, leaving a balance of 4,663 fish for the remainder of the week. CPUE was 100 sockeye/boat/day ( $\mathrm{s} / \mathrm{b} / \mathrm{d}$ ) on day 2 and matched the weekly average of 101. Canyon Island fishwheel CPUE on Sunday, July 11 and Monday, July 12 was 1.3 and 3.8 times average CPUE, respectively. An extension of one day was granted.

It was agreed pre-season that co-ordinated Canada/U.S. actions would be taken during statistical weeks 30 to 33 (starting July 18, 25, August 1 and 8 respectively) in order to protect the Tatsamenie Lake stock, which was anticipated to be very weak. (The preseason forecast, based on smolt emigration estimates, was for a return even lower that that observed in 2003). Unless otherwise agreed to inseason, the U.S was to restrict openings to 2 days in Taku Inlet during weeks 30 to 32; Canada was to so the same for its fishery during weeks 31 to 33 .

Week 30 (starting July 18) opened on three days. At the close of day 2, it was extended by 2 days based on the following: a balance of 1,896 fish showing in the guideline harvest; Canyon Island fishwheel CPUE for July 18 and 19 that was 1.6 and 2.7 times average CPUE, respectively; and average fishery CPUE ( $112 \mathrm{~s} / \mathrm{b} / \mathrm{d}$ versus the weekly average of 117) despite slightly above-average water levels. A total of 3,164 sockeye salmon were caught this opening.

As per the pre-season arrangement, weeks 31 to 33 were opened 2 days, and closed on schedule. At the close of day 1 in week 31, the run projection, cumulative harvest and guideline harvest were $196,088,15,968$ and 13,465 sockeye salmon, respectively. For day 1 in week 32, these values were $105,626,21,139$ and 15,871 , sockeye salmon, respectively. At the close of week 33 , the run projection had increased to 113,297 fish, and the balance in the guideline harvest was 6,671 fish. Fishery performance was average in week 31 ( $130 \mathrm{~s} / \mathrm{b} / \mathrm{d}$ versus 121), slightly below average in week 32 ( 75 versus 111), and $79 \%$ above average in week 33 . Water levels were favourable for all openings. Fishwheel performance for week 31 was $33 \%$ above average (20 sockeye/hour (s/h)
versus 15), for week 32, $22 \%$ below average (11 versus 14); and, for week 33, $56 \%$ above average ( 16 versus 10 ). The total sockeye landing for these three weeks was 6,252 fish.

Week 34 marked the beginning of coho salmon season, and effort was slightly greater than 2003, due to improved market conditions. The coho run projection was approximately 82,000 fish, which was sufficient for the maximum TAC, i.e. 10,000 fish. The fishery was opened on three days and extended by one. Landings of coho salmon and sockeye salmon were 697 and 795 respectively.

Weeks 35 and 36 saw five day openings, with only 2 to four licences fishing. Catches consisted of 2,913 coho salmon and 675 sockeye salmon. These were the last commercial catches of the season, despite the fishery being open for seven days per week through October 10, the close of week 42. A test fishery operated throughout this period for stock assessment purposes and landed 3,266 coho salmon and 72 sockeye salmon.

The cumulative commercial fishery sockeye CPUE for the season was $714 \mathrm{~s} / \mathrm{b} / \mathrm{d}$; below average. CPUE was average to below average throughout the season except for week 33. Peak CPUE was observed in week 31, which is the week in which the fishery has peaked most often over the previous ten years. The fact that water levels dropped from average to well below average over the course of the opening likely had a positive influence on the CPUE this week.

The cumulative coho CPUE through week 36 (when commercial fishing ceased) was 353 coho/boat/day. This was above average.

## Escapement

## Sockeye Salmon

Spawning escapement of sockeye salmon into the Canadian portion of the Taku River drainage is estimated from the joint Canada/U.S. mark-recapture program. Counting weirs operated by DFO at Little Trapper and Tatsamenie lakes provided information on the distribution and abundance of discrete spawning stocks within the watershed. An additional sockeye enumeration program was conducted at Kuthai Lake by the TRTFN, who expanded their operations to King Salmon Lake in 2004 for the second consecutive year.

A mark-recapture program has been operated annually since 1984 to estimate the aboveborder run size (i.e., border escapement); spawning escapement is then estimated by subtracting the inriver catch. The final 2004 estimate of border run was 127,047 sockeye salmon and the spawning escapement was estimated at 106,688 fish (Table 5). This spawning escapement was average (Appendix D.9), and was above the interim escapement goal range of 71,000 to 80,000 sockeye salmon.

The sockeye count through the Kuthai Lake weir was 1,578 fish; below average (Appendix D.10). Migration through the weir did not commence until July 24, three weeks later than average, due to an apparent blockage in the lower part of the Silver Salmon River. Approximately $24 \%$ of the run came through on this date. Opportunistic
aerial inspections indicated that the apparent blockage had worked itself out. The estimated sex composition at the weir was $63 \%$ female ( $\mathrm{n}=550$ ).

The Little Trapper Lake weir count was 9,613 sockeye; below average (Appendix D.10). The estimated sex composition was $50 \%$ female ( $\mathrm{n}=750$ ).

The Tatsamenie Lake weir count in 2004 was 1,951 sockeye salmon. This was below average. The estimated sex composition was $42 \%$ female, i.e. 825 fish ( $n=680$ ). A total of 297 females and 293 males were held for broodstock; 72 females and 57 males were released in mid-October after the egg-take goal was reached. Egg-take details are presented in the enhancement section of this report.

The King Salmon weir count was 5,005 sockeye salmon, an estimated $54 \%$ of which were female. This was a follow-up to last year's pilot in which only part of the migration period was covered. This year the weir was installed on July 6 and pulled on August 29; the entire run was enumerated.

## Chinook Salmon

Spawning escapement of Chinook salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tag application occurred April 30 through mid-July. Tag recovery effort consisted of commercial, test, and aboriginal gillnet fisheries from May 2 through October 10 (statistical weeks 19 to 41) as well as spawning ground sampling in August and September. The final aboveborder escapement was estimated to be 77,936 large (three-ocean and older) Chinook salmon. The final spawning escapement estimate was 75,032 large fish. The spawning escapement of large Chinook salmon was above average, and above the upper end of the escapement goal range of 30,000 to 55,000 fish.

Table 5. Taku River sockeye salmon terminal run reconstruction, 2004. Estimates do not include spawning escapements below the U.S./Canada border.

| Total | 105,031 | 103,841 | 1,190 |  |  |  |
| Total \% | 81.4\% | 82.0\% | 50.0\% |  |  |  |
| Actual | 76,968 | 76,282 | 686 |  |  |  |
| Actual \% | 59.7\% | 60.2\% | 28.8\% |  |  |  |

${ }^{\text {a }}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

Aerial surveys of large Chinook salmon to the six escapement index areas annually surveyed by ADF\&G were as follows: Nakina 4,091 fish, Kowatua 828 fish, Tatsamenie 1,396 fish, Dudidontu 1,036 fish, Tseta, 906 fish, and Nahlin 1,787 fish (Figure 9, Appendix D.11). The total of 10,044 large Chinook salmon observed was above average.

Spawning escapement of coho salmon in the Canadian portion of the Taku drainage was estimated from the joint Canada/U.S. mark-recapture program. Tag application occurred through October 4; recovery occurred through October 10 (both dates are in statistical week 41). The tag recovery effort consisted of commercial and test gillnet fisheries. The final above-border coho run was estimated to be 141,837 fish, and the spawning escapement was estimated at 132,153 fish (Appendix C.7). The spawning escapement
was above average, and was above the upper limit of the interim escapement goal range 27,500 to 35,000 fish.

## Pink Salmon

There is no program to estimate the escapement of Taku River pink salmon; however, the Canyon Island fish wheels provide an index of annual variation in border escapement. A total of 8,464 pink salmon were captured fish wheels in 2004 (Appendix D.14). This was below average.

## Chum Salmon

As with pink salmon, the Canyon Island fish wheels are used to determine annual variations in border escapement. A total of 414 chum salmon were captured in the wheels in 2004; above average (Appendix D.14). The Taku River fall chum run has been depressed since 1988. It is unlikely that the spawning escapement goal of 50,000 to 80,000 chum salmon was achieved in 2004.

#### Abstract

ALSEK RIVER Alsek River salmon stocks contribute to the U.S. commercial gillnet fisheries located in Dry Bay, at the mouth of the Alsek River (Figure 3). Unknown quantities of Alsek River origin fish are also taken in the U.S. commercial gillnet and troll fisheries in the Yakutat area. No commercial fishery exists in the Canadian portions of the Alsek River drainage, although aboriginal and recreational fisheries occur in the Tatshenshini River and some of its headwater tributaries (Figure 3).

Figure 3. The Alsek River and principal U.S. and Canadian fishing areas.

## Harvest Regulations \& Management Objectives

Although catch sharing of Alsek River salmon stocks between Canada and the U.S. has not yet been specified, Annex IV does call for the development and implementation of cooperative abundance-based management plans and programs for Alsek River Chinook salmon, sockeye salmon, and coho salmon. Interim escapement goal ranges for Alsek River sockeye salmon and coho salmon were initially set by the TTC at 33,000 to 58,000 sockeye, and 5,400 to 25,000 coho salmon. The principle escapement-monitoring tool for Chinook salmon, sockeye salmon, and coho salmon stocks on the Alsek River is the Klukshu weir, operated by DFO and the Champagne-Aishihik First Nation (CAFN). The weir has been in operation since 1976. To make the management objectives of Chinook salmon and sockeye salmon better defined, in terms of Klukshu stocks, revised goals,
expressed in terms of Klukshu stocks only, were established in 1999 and adopted again in 2004. Mark-recapture programs to estimate the total inriver abundance and the fraction of the escapement contributed by Klukshu stocks have been in operation since 1997 for Chinook salmon, and since 2000 for sockeye salmon.

The initiative to establish a specific Klukshu Chinook salmon spawning goal began in 1991 when the TTC set an interim spawning objective of 4,700 Klukshu Chinook salmon. This goal was based more on manager's intuition than on science. From 1995 through 1997, the TTC reviewed this escapement level and concluded that goal of 4,700 Chinook salmon was not supported by the data. A new goal range of 1,100 to 2,300 fish was proposed based on joint analyses of stock-recruitment data. The Parties conducted independent internal reviews of these analyses. Although there was not unanimous support for the proposal, there was agreement on establishing a minimum goal consistent with the lower end of the proposed range. As a result, Canadian and U.S. managers agreed to a minimum spawning escapement goal of 1,100 Chinook salmon for the Klukshu system for 2000, and this was used again in the 2004 season.

The stock-recruitment analysis of Klukshu sockeye salmon data has been completed and has undergone internal peer review. The new escapement goal range for Klukshu River sockeye salmon is 7,500 to 15,000 spawners per year.

## Preseason Forecasts

The overall sockeye salmon run to the Klukshu River in 2004 was expected to be below average in strength. Principal contributing brood years to the 2004 run were expected to be 1999 (Klukshu escapement of 5,101 fish) and 2000 (Klukshu escapement of 5,422 fish); average Klukshu escapement was 14,204 fish. Based on historical stockrecruitment analysis, the range of Klukshu escapements that appear most likely to produce maximum sustained yields is 7,500 to 15,000 sockeye salmon.

The 2004 overall Alsek River sockeye salmon run was expected to be approximately 44,670 fish. This estimate was based on: a predicted run of 12,061 Klukshu sockeye salmon derived from the average of the historical Klukshu stock-recruitment data and an assumed Klukshu contribution of $27 \%$ (based on the 2001 to 2003 sockeye radio tagging study). A run size of this magnitude is well below the average run size estimate of 77,200 fish (based on the Klukshu weir count expanded by $1 / 0.27$ to account for other inriver escapement and an assumed U.S. harvest rate of 20\%).

The Klukshu early run sockeye salmon escapements in 1999 and 2000 were 371 fish and 237 fish, respectively (Appendix E.7). Both the 1999 and 2000 escapements were well below the optimum level of 2,500 sockeye salmon spawners as determined through separate stock-recruitment analyses by DFO of the early run. Due to the under escapement in 1999 and 2000, the early run was expected to be well below average.

The Klukshu Chinook salmon escapements in 1998 and 1999, 1,347 and 2,168 fish, respectively, were both well below average (Appendix E.7). The escapements for 1998
and 1999 were near the lower end and the upper end of the optimum escapement range of 1,100 to 2,300 Chinook salmon estimated from current stock-recruitment analysis. As a result, the preliminary outlook was for a near average run. The overall 2004 Alsek River Chinook run was expected to be approximately 15,200 fish. This estimate was based on a predicted run of 2,500 Klukshu Chinook salmon derived from the historical Klukshu stock-recruitment data and an assumed Klukshu contribution to the total run of approximately $17 \%$.

The coho salmon escapements observed at the Klukshu River in 2000 (4,800 coho salmon, but count incomplete) and 2001 ( 750 coho salmon), suggests the run in 2004 would be average (Appendix E.7).

The overall sockeye run to the Klukshu River in 2003 was expected to be slightly above average in strength. Principal contributing brood years to the 2003 run were expected to be 1998 (Klukshu escapement of 13,580 fish) and 1999 (Klukshu escapement of 5,101 fish); the 1993 to 2002 average Klukshu escapement was 12,484 fish. Based on historical stock-recruitment analysis, the range of Klukshu escapements that appear most likely to produce maximum sustained yields is 7,500 to 15,000 sockeye salmon.

## U.S. Fisheries

The Dry Bay commercial set-gillnet fishery harvested 656 Chinook, 18,030 sockeye, and 2,475 coho salmon (Appendices E. 1 to E.4). No pink salmon were harvested, and the chum salmon harvest was minimal.

The Chinook salmon harvest was average, the sockeye and coho harvest were below average. Very little effort was recorded during the coho season due to market conditions. The number of fishing days was 76.5. The total effort expended in the fishery was 280 boat-days; below average.

The Alsek River commercial fishery opened on the first Sunday in June, statistical week 24 (June 6; Appendix E.1). The initial opening was extended to 48 hours. For the next 2 weeks of the season weekly openings were extended to 48 and 72 hours, respectively, as sockeye CPUE remained more than double the average. The fourth and fifth weekly openings were not extended beyond 24 hours when CPUE did not indicate strength to that portion of the run. During the second week of July, the weekly opening was extended to 48 hours, and was then further extended to 72 hours during the third week of July as CPUE remained strong. During the final four weeks of the sockeye season fishing time was maintained at 24 hours with the exception of statistical week 33 when fishing time was extended to 48 hours. The fishery targeted coho salmon after late August and fishing times remained at three days per week for the first three weeks of the coho season. With minimal effort and good coho CPUE, fishing time was opened until further notice to allow harvest opportunity for coho salmon. No effort was recorded on the Alsek after the first week of September.

Historically, a set gillnet fishery targeting on Chinook salmon was conducted during May and early June. Due to depressed runs, the directed fishery has been closed since 1963 and Chinook salmon have only been harvested incidentally during the sockeye salmon fishery in early June. From 1963 through 1997, the early June periods were limited in time in order to reduce the impact on Chinook salmon. With the advent of the new Chinook salmon escapement goal concern for incidentally caught Chinook salmon has diminished, therefore the management of the early June periods was based on sockeye salmon CPUE. Gillnet mesh size was restricted to a maximum of six inches through July 1.

## Canadian Fisheries

The aboriginal fishery harvested an estimated 139 Chinook salmon, 1,875 sockeye salmon, and no coho salmon (Figures 11 to 14, Appendices E. 2 and E.6). The final estimated Chinook salmon harvest was below average. The final sockeye salmon catch was above average.

Final harvest estimates for the Tatshenshini recreational fishery were well below average for Chinook salmon with an estimated 46 retained, well above average for sockeye salmon, with an estimated harvest of 247 sockeye salmon, and near average for coho salmon, with 127 being harvested. The harvest was below average for Chinook, above average for sockeye, and average for coho salmon. By July $20^{\text {th }}$, the lower end of the Chinook escapement goal had been met and projections indicated that the upper end of the escapement goal would be exceeded; therefore, it was decided to increase the daily Chinook limit to 2 (4 in possession). The low Chinook catches may have been attributed to the changed river channel (i.e., fewer holding areas below the Tatshenshini/Klukshu rivers confluence) and to the relocation of the Klukshu weir in 2001, which has allowed migrating salmon to stage further up from Dalton Post in the Klukshu River. In addition, water levels in the Tatshenshini River were slightly above normal and turbidity was high during the peak of the Chinook migration and this may have had a negative effect on the Chinook catches. Retention of sockeye salmon in the Tatshenshini River was permitted starting on August $15^{\text {th }}$ as per regulation. By September $8^{\text {th }}$, the sockeye run forecast was to exceed the upper end of the escapement goal and it was decided to increase the daily sockeye limit to 4 ( 8 in possession) starting on September $11^{\text {th }}$. The preliminary catch data was derived from a creel census in the Dalton Post area and a catch card program conducted by the Yukon Salmon Committee (YSC) and DFO. Weekly estimates and annual comparisons are listed in Appendices E. 2 and E.6.

Management of salmon in the Yukon is a shared responsibility between DFO and the Yukon Salmon Committee (YSC). The YSC was established in 1995 pursuant to the Comprehensive Land Claim Umbrella Final Agreement between the Government of Canada, the Council for Yukon Indians and the Government of the Yukon. The Committee is a public board consisting of ten members, $70 \%$ of which are appointed by Yukon First Nations. Two CAFN members sit on the YSC. Although the Committee currently operates by consensus, the voting structure of the Committee is organized so
that, should a vote be necessary, 50\% of the votes reside with appointees of Yukon First Nations.

The 2004 Alsek-Tatshenshini management plan, adopted by CAFN, YSC, and DFO, was based on the objectives described in the Harvest Regulations \& Management Objectives section above. For Chinook salmon and early run sockeye salmon management, the status of the Klukshu weir counts was to be reviewed on or about July 18 to ensure weir and spawning escapement targets were on track. The status of the late run sockeye salmon would be reviewed the first week of September. Adjustments to inseason fishing regimes in the recreational and aboriginal fisheries would be made if deemed necessary. Other key elements of the plan are described below.

The center of aboriginal fishing activity in the Alsek River drainage occurs at the CAFN village of Klukshu, on the Haines road, about 60 km south of Haines Junction. Salmon are harvested by means of gaff and traditional fish traps as the fish migrate up the Klukshu River into Klukshu Lake. The fishing plan for the aboriginal fishery in the Klukshu River for the period prior to August 15 allowed fishing by means of fish traps for 2 days per week. After August 15, it was planned that the traps would be fished 3 days per week. Conservation thresholds that might invoke restrictions in the Aboriginal fishery were projected Klukshu weir counts of $<1,100$ Chinook salmon, and $<1,500$ early sockeye salmon. Gaff fisheries also exist on Village Creek and in the headwaters of the Tatshenshini River and tributaries thereof (Goat Creek, Stanley Creek, Parton River, and the Blanchard River). The plan did not restrict the gaff fishery, other than to reserve Goat Creek, Stanley Creek, and the Parton River for elders only.

The majority of the recreational fishing effort on this drainage occurs on the Tatshenshini River, at and just downstream of the mouth of the Klukshu River in the vicinity of the abandoned settlement of Dalton Post. The management plan prohibited the retention of sockeye salmon in the recreational fishery prior to August 15 unless the weir count projection for the early run was $>4,500$ sockeye salmon. The Chinook salmon daily catch limit was one fish and the possession limit was 2 fish. For other salmon species, the daily catch and possession limits were 2 and 4 fish, respectively. However, the aggregate limit for all salmon combined was 2 salmon per day, 4 fish in possession. Starting in 2003, recreational salmon fishing was permitted in the Tatshenshini River seven days a week; this fishery had previously been open from 6:00 am Saturday to 12:00 noon Tuesday each week. Headwater areas upstream of the British Columbia/Yukon border were to be closed for the season to protect spawning Chinook salmon. Conservation thresholds that were expected to invoke additional restrictions in the recreational fishery were projected Klukshu weir counts of $<1,500$ Chinook salmon and $<10,600$ sockeye salmon (early and late runs combined).

A mandatory Yukon Salmon Conservation Catch Card (YSCCC), introduced by the YSC in 1999, was required by all recreational salmon fishers in 2004. The purpose of the YSCCC is to improve harvest estimates and to serve as a statistical base to ascertain the importance of salmon to the Yukon recreational fishery. Anglers are required to report
their catch via mail by the late fall. Information requested includes the number, sex, size, date and location of salmon caught and released.

Since 2001, CAFN has imposed a fishing area closure from the Klukshu River Bridge crossing up to the new weir location to allow for better staging opportunities for salmon in the vicinity of the Klukshu/Tatshenshini confluence.

## Escapement

Total drainage abundance programs are being implemented as part of the development of abundance-based management regimes and to accurately assess whether the system-wide escapement goals for Alsek River Chinook salmon and sockeye salmon stocks are appropriate and if so, are being achieved. At this time, there are no programs in place to estimate the drainage-wide coho salmon escapement. A large and variable proportion of the escapement of each species is enumerated at the weir on the Klukshu River. Current escapement monitoring programs including the Klukshu weir, Village Creek electronic counter, and aerial surveys allow annual comparisons of escapement indices. The most reliable long-term comparative escapement index for Alsek River drainage salmon stocks is the Klukshu River weir count. Escapements for 2004 are shown in Table 6.

## Sockeye Salmon

The final weir count was 15,348 and escapement estimate was 13,721 of Klukshu River sockeye salmon (Table 6; Appendices E. 3 and E.7). The count of 3,464 early run fish (count through August 15) was above average while the count of 11,884 late run fish was average. The total escapement was near the, and was in the upper end of the recommended escapement goal range of 7,500 to 15,000 fish. The sockeye salmon escapement estimate at the Village Creek counters of 2,278 fish in 2004; was below average (Appendix E.9).

Table 6. Harvest and Klukshu index escapement data for Alsek River sockeye, Chinook, and coho salmon for 2004.

|  | Sockeye | Chinook | Coho |
| :--- | ---: | ---: | ---: |
| Inriver Run from Mark-Recapture | 68,917 | 7,565 | N/A |
| $\quad$ Escapement Index ${ }^{\text {a }}$ |  |  |  |
| Klukshu Weir Count | 15,348 | 2,525 | 750 |
| $\quad$ Klukshu Escapement | 13,721 | 2,445 | 750 |
| Harvest |  |  |  |
| U.S. Commercial | 18,030 | 656 | 2,475 |
| U.S. Subsistence | 224 | 51 | 21 |
| Canadian Sport | 162 | 77 | 95 |
| Canadian Aboriginal | 1,875 | 139 | 0 |
| Total | 20,291 | 923 | 2,591 |

${ }^{\text {a }}$ Klukshu River salmon stocks represent a large and variable portion of the total Alsek River salmon escapement.
${ }^{\mathrm{b}}$ U.S. harvest estimate differs from Joint Interception Committee estimate because no estimates are made for catches other than the listed fisheries.

A sockeye salmon mark-recapture program was initiated in 2000 to explore the feasibility of developing an abundance-based management regime for Alsek River sockeye salmon and this was continued through 2004. The final modified Petersen estimate of the inriver run above Dry Bay was 70,171 sockeye salmon ( $m=1086$, $r=54$, $\mathrm{c}=3,548$ ), with a $95 \%$ confidence interval of 54,011 to 91,057 fish; Appendix E.8). The Klukshu weir count therefore represented approximately $22 \%$ of the total Alsek inriver sockeye run in 2004. The estimated contribution of Nesketaheen sockeye salmon to the total Alsek River run was approximately $3 \%$.

Historical aerial survey counts for other Alsek River index tributaries are listed in Appendix E.9.

## Chinook Salmon

The most reliable comparative Chinook salmon escapement index for the Alsek River drainage is the Klukshu River weir count. The final Chinook weir count was 2,525 and escapement estimate was 2,445 (Table 6), and both were average (Appendix E.7). The 2004 escapement was above the revised interim escapement goal range of 1,100 to 2,300 Klukshu Chinook salmon.

Aerial Chinook salmon surveys were again flown in 2003. The count of 84 Chinook salmon in the Blanchard River was below average, there was no survey flown for Goat Creek, and the count of 46 fish for the Takhanne River was below average (Appendix E.10).

A Chinook salmon mark-recapture study was conducted again in 2004. The final estimate of inriver run past Dry Bay for Alsek River Chinook salmon was 7,565 large fish (Appendix E.11). The Klukshu escapement of 2,376 large fish represents approximately 33.9\% of the total large Chinook escapement.

## Coho Salmon

The Klukshu coho weir count and escapement of 750 fish below average (Table 6). The weir was removed prior to the completion of the coho salmon run and does not include fish that migrate after mid-October. (Appendix E.12)

## Sockeye salmon Run Reconstruction

Estimates of the Klukshu River contribution to the sockeye salmon run to the Alsek River drainage vary from $14.1 \%$ from the mark-recapture study in 2000 to $38.1 \%$ from the mark-recapture study done in 2003 (Appendix E.8). For 2004, the final estimate of the inriver run above Alsek Lake was 70,171 sockeye salmon (Table 6). The Canadian aboriginal and recreational catch estimates of 2,122 fish left a spawning escapement of 68,049 fish. The estimated U.S. subsistence and commercial catch of 18,030 sockeye salmon added to the inriver run produce a final Alsek total run estimate of 88,201 sockeye salmon (Appendix E.8).

## ENHANCEMENT ACTIVITIES

## Egg Collection

In 2004, sockeye salmon eggs were collected at Tahltan Lake on the Stikine River for the seventeenth year, and in the Tatsamenie Lake system on the Taku River, for the fifteenth year of this program.

## Tahltan Lake

The egg collection was contracted to Arc Environmental Ltd. for the eighth consecutive year. The second large escapement since 1996 provided good numbers of brood stock. Collection of fish was much easier in comparison with recent years. An estimated 5.7 million eggs were collected from 1,936 females and a similar number of males (Appendix F.1). The estimated egg collection was based on eyed-egg processing completed at the hatchery; the average fecundity was 2,785 eggs per female. The brood stock was collected by beach seine at the major spawning site, as has been done in most years. Fish were not collected from other sites due to several constraints. The eggs were collected on thirteen distinct egg-take days. Eggs collected on September 1 and 13 were delayed in shipment to the hatchery by one and 2 days due to weather. The egg-take goal at Tahltan Lake was 6.0 million eggs.

## Tatsamenie Lake

Tatsamenie Lake sockeye brood stock was captured for the tenth year at an adult enumeration weir located at the outlet of Tatsamenie Lake. Egg collection was again contracted to B. Mercer and Associates Ltd. A total of 210 females and 148 males were held prior to the first egg take on September 19. The held brood stock represented 30\% of the 2004 sockeye escapement (1,357 fish) into Tatsamenie Lake (Appendix C.9). An estimated 0.75 million eggs were collected (based on a hatchery estimate of egg counts and a fecundity of 4,223 eggs per female) from 210 females and milt was collected from

148 males during 6 egg collections. Mortality of held fish included 48 females and 83 males; the remaining 129 females and 113 males not used for gamete collection were released on October 18 and it was not known if any of the fish spawned successfully. Investigation of a passive flow incubator continued at the lake with 195,500 eggs collected from 46 females and placed in the incubator on October 10.

## Incubation, Thermal Marking, and Fry Plants (2003 Brood Year)

The egg incubation and thermal-marking program at Snettisham Hatchery went smoothly in year 2003/2004. Snettisham hatchery is operated by DIPAC (Douglas Island Pink and Chum, Inc.), a private aquaculture organization in Juneau. A co-operative agreement between ADF\&G and DIPAC provides for Snettisham hatchery to serve the needs of the joint TBR enhancement projects.

Incubation of 2003 brood eggs took place at Snettisham Hatchery and the resultant fry were transported to the appropriate systems from May 21 to June 12, 2004. An estimated 484,000 Tatsamenie Lake sockeye salmon fry in three incubators were lost to the IHN virus.

## Tahltan Lake

A total of 1.266 (Appendix F.1) million fry from the 2003 Tahltan sockeye egg take was planted back into Tahltan Lake in 2004 (Appendix F. 1 and F.2). Survival from green-egg to outplanted fry was $93.7 \%$. Fry outplanting took place from May 21 to May 28 (Appendix F.1).

## Tuya Lake

There were 3.2 million sockeye fry planted in Tuya Lake on June 12, 2004. These fish were from eggs collected at Tahltan Lake in the fall of 2003. Survival from green-egg to outplanted fry was $88.4 \%$ (Appendix F.2).

## Tatsamenie Lake

A total of 0.92 million sockeye fry from the 2003 egg-take was released into Tatsamenie Lake in 2004, and an additional 0.442 million fry were placed in a net pen in the lake for feeding, but were lost to IHNV. Survival from green-egg to outplanted-fry was $53.6 \%$ (Appendix F.3). Low survival was partially due to loss of three incubators to IHNV. Outplanting took place from May 21 to May 27.

The loss of Tatsamenie fry to IHNV both during incubation at Snettisham and during the net pen rearing at Tatsamenie Lake is an expected consequence of the culture of sockeye salmon. The strategy of compartmentalization and isolation provides assurance that losses are kept to a minimum. The incidence in of the IHN virus in the brood stock was one of the highest we have seen in 2003.

The Appendix F tables summarize enhancement activities for 2004 and prior years.

## Outplant Evaluation Surveys

## Acoustic, Trawl, Beach seine and Limnological Sampling

In 2004, surveys were directed by the Salmon Indexing Methods Unit of Stock Assessment Division of the Pacific Biological Station (PBS) and the Yukon/Transboundary Stock Assessment section of Fisheries and Oceans Canada. Limnological, beach seine, hydroacoustic and trawl surveys were conducted at Tatsamenie Lake by B. Mercer \& Associates. A spring limnological survey that included beach seining was conducted by B. Mercer \& Associates at Tuya Lake and an early August survey that included index netting, hydroacoustic surveys and trawling was conducted by the PBS. Limnological and beach seine surveys were performed at Tahltan Lake by onsite Fisheries and Oceans Canada (DFO) personnel.

## ADF \& G Thermal Mark Laboratory

During the 2004 season the ADFG thermal mark lab received otoliths from 13,085 sockeye salmon collected by ADFG and DFO staff as part of the U.S./Canada fry-planting evaluation program. These collections came from commercial and test fisheries in U.S. waters and in Canadian fisheries on the Taku and Stikine Rivers over a 12-week period. In addition, several escapement samples were examined. Combined, the laboratory processed 12,976 of the otoliths received ( $99 \%$ ) and provided estimates on hatchery contributions for almost 100 distinct sampling collections. Of these totals, 2,260 otoliths were identified and classified as belonging to one of 30 marked groups. Estimates of the percentage of hatchery fish contributed to commercial fishery catches were provided to ADF\&G and DFO fishery managers 24 to 48 hours after samples arrived at the lab.

Adult sockeye salmon otoliths were processed inseason by the ADF\&G otolith lab to estimate the weekly contribution of planted sockeye salmon to the District 106, 108, and 111 gillnet fisheries and to Canadian commercial fisheries in the Stikine and Taku Rivers. Contributions of planted sockeye salmon stocks to catches were as follows: 16,832 planted Stikine River fish to District 106 and 108, and 794 planted Taku River fish to District 111 (includes inriver personal use fishery). Contributions of planted sockeye salmon stocks in the Canadian fisheries included 16,800 to Stikine River fisheries and 283 planted Taku River fish to the Taku River fisheries.

## Canadian Thermal Mark Laboratory

Sub-samples of juvenile and adult otolith samples collected at the study lakes during the 2004 season were analyzed at the DFO thermal mark lab in Whitehorse.

## APPENDICES

## Standards

Large Chinook salmon are MEF length $\geq 660$
Unless otherwise stated Chinook salmon are large
Data not available to estimate catches of Alaska Hatchery pink and chum salmon

All catches of Tahltan, Trapper, and Tatsamenie, unless otherwise noted, include both wild and hatchery fish.

Appendix A. 1. Weekly salmon catch in the Alaskan District 106 commercial drift gillnet fisheries, 2004.

Appendix A. 16. Weekly catch, CPUE, and migratory timing of Tahltan, Tuya, and mainstem sockeye stocks in the Stikine test fishery, 2004.
Sex specific age compositions were calculated and the smoothed stock compositions of the females sampled for egg diameters was expanded to the catch by age. If no test fishery, commercial catch from comparable week is used.

Appendix B. 11. Stock specific catches of sockeye salmon in the Alaskan Districts 106 and 108 test fisheries, 1984-2004.
Table only includes years when test fisheries were operated and catches included sockeye salmon.
Data based on scale pattern analysis.

Appendix B. 24. Aerial survey counts of Mainstem sockeye stocks in the Stikine River drainage, 19842004.

The index represents the combined counts from eight spawning areas.
Survey conditions were exceptionally poor; therefore, the counts probably did reflect relative abundance.

Appendix B. 25. Estimates of sockeye salmon smolts migrating through Tahltan Lake smolt weir, 19842004.

Appendix D. 1. Salmon catches and effort in the Alaskan District 111 commercial drift gillnet fishery, 1960-2004.
S. Chum and F. Chum refer to Summer and Fall runs of these fish, fish harvested prior to week 34 are considered summer chum, and fish harvested in week 34 and beyond are considered fall chum.
Days open are for the entire district and include openings to harvest spawner chinook salmon, 1960-1975.

| Year | Catch |  |  |  |  |  | Effort |  |

Appendix D. 4. Salmon catch in the U.S. subsistence and personal use fisheries in the Taku River, 19672004.

The subsistence fishery was open 1967 to 1976 and 1985 and the personal use fishery was open 1989-2010. The harvests are miminum estimates because not all permits are filled out and returned.

[^2]Appendix D. 9. Taku River sockeye salmon run size, 1984-2004.
Run estimate does not include spawning escapements below the U.S./Canada border. The early season sockeye expansion is based on the proportion of fish wheel sockeye catch that occurs before the fishery opens.

Appendix D. 10. Sockeye salmon escapement estimates of Taku River and Port Snettisham sockeye stocks, 1979-2004.

Appendix D. 11. Taku River Chinook salmon run size, 1979-2004.
The run estimates do not include spawning escapements below the U.S./Canada border.
Estimates are expanded if mark-recapture activities terminate prior to run completion.

Appendix D. 14. Escapement counts of Taku River coho salmon, 1984-2004.
Counts are for age-. 1 fish and do not include jacks. Because of variability between methods, visibility, observers, and timing,
these counts are not an index of run strength.

${ }^{\mathrm{a}}$ Weir was removed prior to the end of the coho run.
${ }^{\mathrm{b}}$ The chinook and sockeye escapements into Klukshu Lake are calculated from the weir count minus fish harvested above the weir site minus broodstock taken. The remainder of the food fishery harvest occurred below the weir, at Village Creek, and Blanchard and Takhanne Rivers.
${ }^{\text {c }}$ Includes sockeye counts up to and including August 15.

Appendix E. 8. Alsek River sockeye escapement 200-2004. Estimates are based on a mark-recapture study.

${ }^{\text {a }}$ Eggs not transported but placed in inlake incubator; $2000=244,000,2001=865,000,2002$ 196,000, $2003=190,000$.
${ }^{\mathrm{b}}$ Survival rates are for hatchery eggs and hatchery fry plants and do not inlcude the lake incubators.
${ }^{\text {c }}$ All died to IHNV

[^0]:    ${ }^{\text {a }}$ Includes an estimated 2,285 thermally marked Tuya fish.

[^1]:    ${ }^{\text {a }}$ The Trapper and Mainstem groups were combined in the 1989 analysis with 13,792 fish or .744 proportion.
    ${ }^{\mathrm{b}}$ Averages do not include 1989.

[^2]:    ${ }^{2}$ Incomplete harvest data.

[^3]:    ${ }^{\text {a }}$ All eggs collected in 2000 and 2001 were for backplant into Tahltan Lake.
